   - Using Talpo
   - Modularity

4. Conclusion
Opinions expressed here are only mine!

- not of my employer (CEA, LIST) or school (Polytech Tours)
- not of the GCC community
- not of funding agencies (e.g. DGCIS or Google GSOC)

I don’t understand or know all of GCC; there are many parts of GCC I know nothing about.

Beware that I have some strong technical opinions which are not the view of the majority of contributors to GCC.

I am not a lawyer \(\Rightarrow\) don’t trust me on licensing issues

(slides presented before at Archi11 (Basile), and RMLL11 (Pierre))

---

\(^1\)Work on Melt have been possible thru the GlobalGCC ITEA and OpenGPU FUI collaborative research projects, with funding from DGCIS, and GSOC (for Talpo)
Questions to the audience

1. What is your usual Gcc version? your latest Gcc?
2. Who contributed to Gcc?
3. Who knows and codes in
   - C language is mandatory since you use gcc!
   - C++ or Objective C or D or Go or OpenCL or Cuda (C “improvements”)?
   - Scheme, Common Lisp, Clojure, or Emacs Lisp (lispy languages)?
   - Ocaml or Haskell or Scala (pattern matching, functional)?
   - Java or C# [.Net] (major VMs, GC-ed)?
   - Python, Ruby, Lua, PHP, Perl, Awk, Scilab, R (dynamic scripting languages)?
   - Fortran, Ada, Pascal, Modula3 (legacy, perhaps targeted by Gcc)?
4. Who wrote (or contributed to) a compiler? An interpreter? A C or JIT code generator?
Contributing to GCC

**Bug reports** are always welcome. [http://gcc.gnu.org/bugzilla/](http://gcc.gnu.org/bugzilla/) give carefully all needed information

For **code** (or documentation) **contributions**:

- legalese: **copyright assignment** of your work to FSF
  - need legal signature by important people: boss, dean, “President d’Université” (takes a lot of bureaucratic time)
  - never submit code which you did not write yourself
- **coding rules and standards**
- **peer-review of submitted code patches** on gcc-patches@gcc.gnu.org every contribution to Gcc has been reviewed
GCC at a glance

You are expected to know about it, and to have used it!

http://gcc.gnu.org/

GNU Compiler Collection
(long time ago, started as Gnu C Compiler)

- Gcc is a [set of] compiler[s] for several languages and architectures with the necessary language and support libraries (e.g. libstdc++, etc.)
- Gcc is free -as in speech- software (mostly under GPLv3+ license)
- Gcc is central to the GNU movement, so ...
- Gcc is a GNU software
- Gcc is used to compile a lot of free (e.g. GNU) software, notably most of GNU/Linux distributions, Linux kernel, ...
- the http://www.gnu.org/licenses/gcc-exception.html permit you to use Gcc to compile proprietary software with conditions.
  So, it probably forbids to distribute only binaries built with a proprietary enhancement of Gcc.

Everyone is using code compiled with Gcc
(e.g. in your smartphone, car, plane, ADSL box, laptop, TV set, Web servers ...).
A short history of GCC

- started in 1985-87 by RMS (Richard M. Stallman, father of GNU and FSF)
- may 1987: gcc-1.0 released (a “statement at a time” compiler for C)
- december 1987: gcc-1.15.3 with g++
- 1990s: the Cygnus company (M. Tiemann)
- february 1992: gcc-2.0
- 1997: The EGCS crisis (an Experimental Gnu Compiler System), a fork
- ecgs 1.1.2 released in march 1999
- april 1999: ECGS reunited with FSF, becomes gcc-2.95
- march 2001: gcc-2.95.3
- june 2001: gcc-3.0
- november 2004: gcc-3.4.3
- april 2005: gcc-4.0
- april 2010: gcc-4.5 enable plugins and LTO
- march 2011: gcc-4.6 released

See also [http://www.h-online.com/open/features/GCC-We-make-free-software-affordable-1066831.html](http://www.h-online.com/open/features/GCC-We-make-free-software-affordable-1066831.html)
GCC community

The community:

- more than 400 contributors (file MAINTAINERS), mostly nearly full-time corporate professionals (AMD, AdaCore, CodeSourcery, Google, IBM, Intel, Oracle, SuSE, and many others)
- copyright assigned to FSF (sine qua non for write svn access)
- peer-reviewed contributions, but no single leader
- several levels:
  1. Global Reviewers (able to Ok anything)
  2. Specialized Reviewers (port, language, or features maintainers)
  3. Write After Approval maintainers
     (formally cannot approve patches, but may comment about them)

These levels are implemented socially, not technically
(e.g. every maintainer could svn commit any file but shouldn’t.).

Public exchanges thru archived mailing-lists gcc@gcc.gnu.org & gcc-patches@gcc.gnu.org, IRC, meetings, GCC Summit-s.
GCC Steering Commitee

The SC is made of major Gcc experts (mostly global reviewers, not representing their employers). It takes major “political” decisions:

- relation with FSF
- license update (e.g. GPLv2 → GPLv3) and exceptions
- approve (and advocate) major evolutions: plugins feature\(^2\), new languages, new targets
- nominate reviewers

NB. Major technical improvements (e.g. LTO or Gimple) is not the role of the SC.

\(^2\)The introduction of plugins required improvement of the GCC runtime exception licensing.
GCC major features

- **large free software** project, essential to GNU ideals and goals
  - old mature software: **started in 1984**, lots of legacy
  - essential to free software: **corner stone of GNU** and Linux systems
  - big software, nearly **5 million lines** of source code
  - **large community** (≈ 400) of full-time developers
  - **no single leader** or benevolent dictator
    ⇒ the GCC code base or architectural design is sometimes messy!

- compiles **many source languages**: C, C++, Ada, Fortran, Objective C, Java, Go . . . (supports several standards, provides significant extensions)

- makes non-trivial **optimizations** to generate **efficient binaries**

- **targets many processors** & variants: x86, ARM, Sparc, PowerPC, MIPS, . . .

- can be used as a **cross-compiler**:
  - compile on your Linux PC for your ARM smartphone

- can **run on many systems** (Linux, FreeBSD, Windows, Hurd . . .) and generate various binaries
Extending GCC

Recent GCC can be extended by plugins. This enables extra-ordinary features:

- **additional optimizations** (e.g. research or prototyping on optimizations)
- **domain-, project-, corporation-, software- ... specific extensions:**
  1. specific warnings, e.g. for untested calls to `fopen` or `fork`
  2. specific type checks, e.g. type arguments of variadic `g_object_set` in `Gtk`.
  3. coding rules validation, e.g. ensure that `pthread_mutex_lock` is matched with `pthread_mutex_unlock`
  4. specific optimizations, e.g. `fprintf(stdout,...) ⇒ printf(...)`
- take advantage of GCC power for your “source-code” processing (metrics, navigations, refactoring...)

Some people dream of enhancing GCC thru plugins to get a free competitor to **Coverity**
http://www.coverity.com/ **source code analyzer**
See also a C-only free static analyzer **Frama-C** http://frama-c.com/ coded in Ocaml
alternatives to GCC

You can use other languages:

1. high-level functional statically-typed languages like e.g. Ocaml [http://caml.inria.fr](http://caml.inria.fr) or Haskell
2. more academic languages (SML, Mercury, Prolog, Scheme, ...)  
3. or niche languages (Erlang ...)
4. dynamic scripting languages: Python, PHP, Perl, Lua ...
5. dynamic compiled languages: Smalltalk (Squeak), CommonLisp (SBCL)  
(some implementations are even generating machine code on the fly!)
6. Java and JVM based languages (Scala, Clojure, ...)
7. etc ...

assembly code is obsolete: compilers do better than humans  
(you could use Gcc powerful asm statement)

---

3 Some compilers - e.g. Chicken Scheme- are generating C code for Gcc
4 Gcc accepts Java as gcj but that is rarely used.
5 For a hundred lines of code.
Generating code yourself

You can generate code, either e.g. C or C++\(^6\), or machine code with JIT-ing libraries like GNU `lightning` or `libjit` or LLVM, a free BSD-licensed\(^7\) library [http://llvm.org](http://llvm.org) for [machine] code generation (e.g. Just In Time)

Melt is implemented by generating C code

**meta-knowledge**\(^8\) **meta-programming** and *multi-staged programming* are interesting subjects.

Advice: never generate by naïve text expansion (e.g. printf...). Always represent your generated code in some abstract syntax tree.

\(^6\) You could even generate C code, compile it (by forking a `gcc` or a `make`), then `dlopen` it, all from the same process. On Linux you can call `dlopen` many times.

\(^7\) IMHO, the BSD license of LLVM do not encourage enough a free community. LLVM is rumored to have many proprietary enhancements.

\(^8\) J.Pitrat: *Méta-connaissances, futur de l’intelligence artificielle* (Hermès 1990)

*Artificial beings - the conscience of a conscious machine* (Wiley 2009)
Competitors to GCC

You can use other compilers, even for C or C++:

- proprietary compilers, e.g. Intel’s *icc*
- **Compcert** [http://compcert.inria.fr/](http://compcert.inria.fr/) - a C compiler formally proven in Coq (restrictive license, usable & readable by academia)
- **Clang**, a C and C++ front-end above LLVM.
- “toy” one-person compilers⁹, usually only on x86:

NB: There is almost no market for costly proprietary compilers, competitors to GCC

Competition is IMHO good within free software

---

⁹Often quite buggy in practice
Why GCC matters?

GCC matters to you and to me because:

- you are interested in computer architecture or performance or diagnostics\(^1\), so compilers matter to you
- you want to experiment some new compilation ideas
- you want to profit of GCC to do some “extra-compilatory” activities
- so you need to understand (partly) GCC internals
- it is fun to understand such a big free software!
- you want to contribute to GCC itself (or to Melt)

\(^1\) Execution speed, code size, fancy compiler warnings!
Link time or whole program optimization

Recent GCC has **link-time optimizations**: use `gcc -O2 -flto` for compile **and** for linking\(^\text{11}\).

Then optimization between compilation units (e.g. inlining) can happen.

LTO can be costly.

LTO is implemented by encoding GCC internal representations (Gimple, ...) in object files.

LTO can be extended for large whole program optimization (WHOPR)

LTO can be used by extensions to provide **program-wide** features

\(^{11}\) e.g. with `CC=gcc -O2 -flto` in your **Makefile**
Gcc and Melt big picture

250 passes in GCC!

bee.c  C front-end
foo.cc  C++ front-end
bar.f90  Fortran front-end
cat.adb  Ada front-end
dog.o  LTO “front-end”

GCC   MELT

Basile STARYNKEVITCH, Pierre VITTET
GCC plugins and MELT extensions (e.g. Talpo)
August 24th 2011 GHM’11
What is MELT?

Coding Gcc extensions (or prototyping new Gcc passes) is quite difficult in C:

- compiler technology is mostly symbolic processing
  (while C can be efficient, it is not easy to process complex data with it).
- specific Gcc extensions need to be developed quickly
  (so development productivity matters more than raw performance)
- an important part of the work is to detect or filter patterns in Gcc internal representations

Melt is a lispy Domain Specific Language for developing Gcc extensions

- Melt is designed to fit very well into Gcc internals; it is translated to C
  (in the style required by Gcc).
- Melt has powerful features: pattern-matching, applicative & object programming, . . .
- Melt is itself a [meta-] plugin\(^{12}\) for Gcc

\(^{12}\)There is also an experimental Gcc branch for Melt!
driven by gcc

gcc -v -O hello.c -o hello

1 C-compile
/usr/lib/gcc/x86_64-linux-gnu/4.6.1/ccl -quiet -v hello.c -quiet \
-dumpbase hello.c -mtune=generic -march=x86-64 -auxbase hello \ 
-O -version -o /tmp/ccTBI9E6.s

2 assemble
as -64 -o /tmp/ccOMVPbN.o /tmp/ccTBI9E6.s

3 link
/usr/lib/gcc/x86_64-linux-gnu/4.6.1/collect2 --build-id \

Introduction

running GCC

driven by \texttt{gcc} [with \texttt{C++} and \texttt{LTO}]

gcc -v -O -flto sayit.cc hello1.c -o hello1 -lstdc++

1. C++ compile

   .../\texttt{cc1plus} -quiet -v -v -D\_GNU\_SOURCE sayit.cc -quiet -dumpbase sayit.cc -mtune=generic -march=x86-64

2. assemble \texttt{as} -64 -o /tmp/ccMj0zRK.o /tmp/cccEErWK.s

3. C compile

   .../\texttt{cc1} -quiet -quiet -v -v hello1.c -quiet -dumpbase hello1.c -mtune=generic -march=x86-64

4. assemble \texttt{as} -64 -o /tmp/ccocvgSK.o /tmp/cccEErWK.s

5. link

   .../\texttt{collect2} -plugin .../\texttt{liblto\_plugin.so} -plugin-opt=.../\texttt{lto\_wrapper} -plugin-opt=-frtti

6. re-invoke \texttt{gcc} @/tmp/ccZF9We9.args so

1. \texttt{link\_time optimize}

   .../\texttt{lto1} -quiet -dumpdir ./ -dumpbase hello1.wpa -mtune=generic -march=x86-64

2. \texttt{link\_time optimize}

   .../\texttt{lto1} -quiet -dumpdir ./ -dumpbase hello1.ltrans0 -mtune=generic -march=x86-64

3. assemble \texttt{as} -64 -o /tmp/ccBc8K58.ltrans0.ltrans.o /tmp/ccghYRNa.s
what is happening inside cc1?

make inside a **fresh directory** a small hello.c with a simple loop, and using `#include <stdio.h>`

- compile with `gcc -v -Wall -O hello.c -o hello` and run `./hello`
- preprocessing: `gcc -C -E hello.c > hello.i`. **Look into** `hello.i`
- generated assembly: `gcc -O -fverbose-asm -S hello.c`. *See hello.s. Try again with* `-g` or `-O2 -mtune=native`
- detailed timing report with `-ftime-report`. **Try it with** `-O1` and with `-O3`
- internal dump files, to debug or understand Gcc itself.
  `gcc -O2 -c -fdump-tree-all hello.c` produces hundreds of files. List them **chronologically** with `ls -lt hello.c.*` and look inside some.
1 Introduction
   • about you and me
   • about GCC and MELT
   • running GCC

2 MELT
   • why MELT?
   • handling GCC internal data with MELT
   • matching GCC data with MELT
   • future work on MELT

3 Talpo
   • Foreword about Talpo
   • Type of tests
   • Using Talpo
   • Modularity

4 Conclusion
Motivations for MELT

Gcc extensions address a limited number of users\(^\text{13}\), so their development should be facilitated (cost-effectiveness issues)

- extensions should be \([\text{meta-}]\) plugins, not Gcc variants \([\text{branches, forks}]\)\(^\text{14}\) which are never used
  ⇒ extensions delivered for and compatible with Gcc releases
- when understanding Gcc internals, coding plugins in plain C is very hard (because C is a system-programming low-level language, not a high-level symbolic processing language)
  ⇒ a higher-level language is useful
- garbage collection - even inside passes - eases development for (complex and circular) compiler data structures
  ⇒ Ggc is not enough : a G-C working inside passes is needed
- Extensions filter or search existing Gcc internal representations
  ⇒ powerful pattern matching (e.g. on Gimple, Tree-s, …) is needed

\(^{13}\)Any development useful to all Gcc users should better go inside Gcc core!
\(^{14}\)Most Gnu/Linux distributions don’t even package Gcc branches or forks.
Embedding a scripting language is impossible

Many scripting or high-level languages can be embedded in some other software: Lua, Ocaml, Python, Ruby, Perl, many Scheme-s, etc...

But in practice this is not doable for Gcc (we tried one month for Ocaml):

- mixing two garbage collectors (the one in the language & Ggc) is error-prone
- Gcc has many existing GTY-ed types
- the Gcc API is huge, and still evolving
  (glue code for some scripting implementation would be obsolete before finished)
- since some of the API is low level (accessing fields in struct-s), glue code would have big overhead ⇒ performance issues
- Gcc has an ill-defined, non “functional” [e.g. with only true functions] or “object-oriented” API; e.g. iterating is not always thru functions and callbacks:

```c
/* iterating on every gimple stmt inside a basic block bb */
for (gimple_stmt_iterator gsi = gsi_start_bb (bb);
     !gsi_end_p (gsi); gsi_next (&gsi)) {
  gimple stmt = gsi_stmt (gsi); /* handle stmt ...*/ }
```

Pedantically, languages’ implementations can be embedded!
Melt, a Domain Specific Language translated to C

Melt is a DSL translated to C in the style required by Gcc

- C code generators are usual inside Gcc
- the Melt-generated C code is designed to fit well into Gcc (and Ggc)
- mixing small chunks of C code with Melt is easy
- Melt contains linguistic devices to help Gcc-friendly C code generation
- generating C code eases integration into the evolving Gcc API

The Melt language itself is tuned to fit into Gcc
In particular, it handles both its own Melt values and existing Gcc stuff

The Melt translator is bootstrapped, and Melt extensions are loaded by the melt.so plugin

With Melt, Gcc may generate C code while running, compiles it\(^{16}\) into a Melt binary .so module and dlopen-s that module.

\(^{16}\)By invoking make from melt.so loaded by cc1; often that make will run another gcc -fPIC
Melt values vs Gcc stuff

Melt handles **first-citizen Melt values:**
- values **like many scripting languages have** (Scheme, Python, Ruby, Perl, even Ocaml . . .)
- **Melt values are dynamically typed**\(^{17}\), organized in a lattice; **each Melt value has its discriminant** (e.g. its class if it is an object)
- you should prefer dealing with Melt values in your Melt code
- values have their **own garbage-collector** (above Ggc), invoked implicitly

But **Melt** can also handle ordinary **Gcc stuff:**
- stuff is usually any **GTY-ed Gcc raw data**, e.g. **tree**, **gimple**, **edge**, **basic_block** or even **long**
- stuff is **explicitly typed** in Melt code thru **c-type annotations** like **:tree**, **:gimple** etc.
- adding new ctypes is possible (some of the Melt runtime is generated)

---

\(^{17}\)Because designing a type-system friendly with **Gcc** internals mean making a type theory of **Gcc** internals!
### Things = (Melt Values) ∪ (Gcc Stuff)

<table>
<thead>
<tr>
<th>things</th>
<th><strong>Melt values</strong></th>
<th><strong>Gcc stuff</strong></th>
</tr>
</thead>
<tbody>

Basile Starynkevitch, Pierre Vittet

GCC plugins and MELT extensions (e.g. Talpo)
Melt garbage collection

- co-designed with the Melt language
- co-implemented with the Melt translator
- manage only Melt values
  all Gcc raw stuff is still handled by Ggc
- **copying generational Melt garbage collector** (for Melt values only):
  1. values quickly allocated in birth region
     (just by incrementing a pointer; a Melt GC is triggered when the birth region is full.)
  2. handle well very temporary values and local variables
  3. minor Melt GC: scan local values (in Melt call frames), copy and move them out of birth region into Ggc heap
  4. full Melt GC = minor GC + ggc_collect (); ¹⁸
  5. all local pointers (local variables) are in Melt frames
  6. needs a write barrier (to handle old → young pointers)
  7. requires tedious C coding: call frames, barriers, normalizing nested expressions
     \( z = f(g(x), y) \rightarrow \text{temporary } \tau = g(x); \quad z = f(\tau, y); \)
  8. well suited for generated C code

¹⁸So Melt code can trigger Ggc collection even inside Gcc passes!
Nothing meaningful, to give a **first taste of Melt language**:

```lisp
;;; -*- lisp -*- MELT code in firstfun.melt
(defun foo (x :tree t)
  (tuple x
    (make_tree descr_tree t)))
```

- comments start with `;` up to EOL; case is not meaningful: `defun` ≡ `deFUn`
- **Lisp-like syntax**: `( operator operands ... )` so parenthesis are always significant in Melt `(f) ≠ f`, but in C `f() ≠ f ≡ (f)`
- `defun` is a “macro” for **defining functions** in Melt
- Melt is an **expression based language**: everything is an expression giving a result
- `foo` is here the name of the defined function
- `(x :tree t)` is a formal arguments list (of two formals `x` and `t`); the “ctype keyword” `:tree` qualifies next formals (here `t`) as raw Gcc tree-s **stuff**
- `tuple` is a “macro” to **construct a tuple** value - here made of 2 component values
- `make_tree` is a “primitive” operation, to **box** the raw tree stuff `t` **into a value**
- `descr_tree` is a “**predefined value**”, a discriminant object for boxed tree values
generated C code from previous example

The [low level] C code, has **more than 680 lines** in generated **firstfun.c**, including

```c
melt_ptr_t MELT_MODULE_VISIBILITY

  ((meltmultiple_ptr_t) (/*_.TUPLREC__V5*/ meltfptr[4])
    (melt_ptr_t) (/*_.MAKE_TREE__V3*/ meltfptr[2]));
meltgc_touch (/*_.TUPLREC__V5*/ meltfptr[4]);
/*_.RETVAL___V1*/ meltfptr[0] = /*_.TUPLE___V4*/ meltfptr[3];
}
```
“hello world” in Melt, a mix of Melt and C code

```melt
;; file helloworld.melt

(code_chunk helloworldchunk
  # { /* our $HELLOWORLDCHUNK */ int i=0;
    $HELLOWORLDCHUNK#_label:
    printf("hello world from MELT %d\n", i);
    if (i++ < 3) goto $HELLOWORLDCHUNK#_label; } # )
```

- **code_chunk** is to Melt what **asm** is to C: for **inclusion** of chunks in the **generated** code (C for Melt, assembly for C or gcc); rarely useful, but we can’t live without!
- **helloworldchunk** is the **state symbol**; it gets **uniquely expanded** in the generated code (as a C identifier unique to the C file)
- `{` and `}`# delimit **macro-strings**, lexed by Melt as a list of symbols (when prefixed by $) and strings: `{A"$B#C" \n"} # ≡ ("A\"" b "C\" \n") [a 3-elements list, the 2nd is symbol b, others are strings]

---

19Like Gcc predefined macro **__COUNTER__** or Lisp’s gensym
running our `helloworld.melt` program

Notice that it has no `defun` so don’t define any `Melt` function.
It has one single expression, useful for its side-effects!

With the Melt **branch**:

```sh
gcc-melt -fmelt-mode=runfile \ 
   -fmelt-arg=helloworld.melt -c example1.c
```

With the Melt **plugin**:

```sh
gcc-4.6 -fplugin=melt -fplugin-arg-melt-mode=runfile \ 
   -fplugin-arg-melt-arg=helloworld.melt -c example1.c
```

Run as

```sh
ccl: note: MELT generated new file  
   /tmp/GCCMeltTmpdir-1c5b3a95/helloworld.c

ccl: note: MELT has built module  
   /tmp/GCCMeltTmpdir-1c5b3a95/helloworld.so in 0.416 sec.

hello world from MELT
hello world from MELT
hello world from MELT
hello world from MELT

ccl: note: MELT removed 3 temporary files  
   from /tmp/GCCMeltTmpdir-1c5b3a95
```
How Melt is running

- Using Melt as plugin is the same as using the Melt branch: $\forall \alpha \forall \sigma \neg fmelt-\alpha=\sigma$ in the Melt branch
  $\equiv \neg fplugin-arg-melt-\alpha=\sigma$ with the melt.so plugin

- for development, the Melt branch\(^{20}\) could be preferable (more checks and debugging features)

- Melt don’t do anything more than Gcc without a mode
  - so without any mode, gcc-melt $\equiv$ gcc-trunk
  - use $\neg fmelt-mode=help$ to get the list of modes
  - your Melt extension usually registers additional mode[s]

- Melt is not a Gcc front-end
  so you need to pass a C (or C++, ...) input file to gcc-melt or gcc
  often with $-c$ empty.c or $-x$ c /dev/null
  when asking Melt to translate your Melt file

- some Melt modes run a make to compile thru gcc -fPIC the
  generated C code; most of the time is spent in that make compiling
  the generated C code

\(^{20}\)The trunk is often merged (weekly at least) into the Melt branch
Melt modes for translating *.melt files

(usually run on empty.c)

The name of the *.melt file is passed with\texttt{-fmelt-arg=filename.melt}

The mode $\mu$ passed with\texttt{-fmelt-mode=\mu}$

- \texttt{runfile} to translate into a C file, make the \texttt{filename.so} Melt module, load it, then discard everything.
- \texttt{translatedebug} to translate into a .so Melt module built with\texttt{gcc -fPIC -g}
- \texttt{translatefile} to translate into a .c generated C file
- \texttt{translatetomodule} to translate into a .so Melt module (keeping the .c file).

Sometimes, several C files \texttt{filename.c, filename+01.c, filename+02.c, ...} are generated from your \texttt{filename.melt}

A single Melt module \texttt{filename.so} is generated, to be \texttt{dlopen}-ed by Melt you can pass\texttt{-fmelt-extra=\mu_1:\mu_2} to also load your $\mu_1$ & $\mu_2$ modules
expansion of the code\_chunk in generated $C$

389 lines of generated $C$, including comments, `#line`, empty lines, with:

```c
{
#ifndef MELTGCC_NOLINENUMBERING
#line 3
#endif

int i=0; /* our HELLOWORLDCHUNK\_1 */
    HELLOWORLDCHUNK\_1\_label: printf("hello world from MELT\n");
    if (i++ < 3) goto HELLOWORLDCHUNK\_1\_label; ;
}
```

Notice the unique expansion HELLOWORLDCHUNK\_1 of the state symbol helloworldchunk

Expansion of code with holes given thru *macro-strings* is central in Melt
Why Melt generates so many C lines?

- **normalization** requires lots of temporaries
- **translation** to C is “straightforward” 😊
- the **generated C code is very low-level!**
- code for **forwarding local pointers** (for Melt copying GC) is generated
- most of the code is in the **initialization**:
  - the generated `start_module_melt` takes a parent environment and produces a new environment
  - uses hooks in the `INITIAL_SYSTEM_DATA` predefined value
  - creates a new environment (binding **exported** variables)
  - **Melt** don’t generate any “data” : all the data is built by (sequential, boring, huge) code in `start_module_melt`
- the **Melt** language is higher-level than C
- ratio of 10-35 lines of generated C code for one line of **Melt** is not uncommon
- ⇒ the **bottleneck** is the **compilation by gcc -fPIC thru make of the generated C code**
Gcc internal representations

Gcc has several “inter-linked” representations:

- **Generic** and **Tree**-s in the front-ends
  (with language specific variants or extensions)
- **Gimple** and others in the middle-end
  - **Gimple** operands are **Tree**-s
  - Control Flow Graph **Edge**-s, **Basic Block**-s, **Gimple Seq**-ences
  - use-def chains
  - **Gimple/SSA** is a **Gimple** variant
- **RTL** and others in the back-end

A given representation is defined by many **GTY**-ed C types
(discriminated unions, “inheritance”, . . .)

*tree, gimple, basic_block, gimple_seq, edge . . . are typedef-ed pointers*

Some representations have various roles
**Tree** both for declarations and for **Gimple** arguments
in gcc-4.3 or before **Gimples** were **Trees**
Why a Lisp-y syntax for Melt

True reason: I [Basile] am lazy 😊, also

- Melt is bootstrapped
  - now Melt translator\(^{21}\) is written in Melt
    \[\text{\$GCCMELTSOURCE/gcc/melt/warmelt-*.melt}\]
    \[\Rightarrow \text{the C translation of Melt translator is in its source repository}^{22}\]
    \[\text{\$GCCMELTSOURCE/gcc/melt/generated/warmelt-*.c}\]
  - parts of the Melt runtime (G-C) are generated
    \[\text{\$GCCMELTSOURCE/gcc/melt/generated/meltrunsup*.\[ch\]}\]
  - major dependency of Melt translator is Ggc\(^{23}\)
- reading in melt-runtime.c Melt syntax is nearly trivial
- as in many Lisp-s or Scheme-s, most of the parsing work is done by macro-expansion \[\Rightarrow \] modular syntax (extensible by advanced users)
- existing support for Lisp (Emacs mode) works for Melt
- familiar look if you know Emacs Lisp, Scheme, Common Lisp, or Gcc .md

\(^{21}\)Melt started as a Lisp program
\(^{22}\)This is unlike other C generators inside Gcc
\(^{23}\)The Melt translator almost don’t care of tree-s or gimple-s
Why and how Melt is bootstrapped

- Melt **delivered** in both **original** `.melt` & **translated** `.c` forms
  - gurus could **make upgrade-warmelt** to regenerate all generated code in source tree.
- at installation, Melt translates itself several times
  - (most of installation time is spent in those [re]translations and in compiling them)
- ⇒ the Melt translator is a good test case for Melt;
  - it exercises its runtime and itself (and Gcc do likewise)
- historically, Melt translator written using less features than those newly implemented (e.g. pattern matching rarely used in translator)
main Melt traits [inspired by Lisp]

- **let**: define *sequential local bindings* (like `let*` in Scheme) and evaluate sub-expressions with them
- **letrec**: define co-*rec*ursive local constructive bindings
- **if**: simple *conditional expression* (like `?:` in C)
- **cond**: complex *conditional expression* (with several conditions)
- **instance**: build dynamically a new Melt object
- **definstance**: define a static instance of some class
- **defun**: define a named function
- **lambda**: build dynamically an anonymous function closure
- **match**: for *pattern-matching*\(^\text{24}\)
- **setq**: assignment
- **forever**: infinite loop, exited with `exit`
- **return**: return from a function
  - may return several things at once (primary result should be a value)
- **multicall**: call with several results

\(^{24}\) a huge generalization of `switch` in C
non Lisp-y features of Melt

Many linguistic devices to describe how to generate C code

- **code_chunk** to include bits of C
- **defprimitive** to define primitive operations
- **defciterator** to define iterative constructs
- **defcmatcher** to define matching constructs

Values vs stuff:

- **c-type** like :tree, :long to annotate stuff (in formals, bindings, ...) and :value to annotate values
- **quote**, with lexical convention ‘α ≡ (quote α)
  - (quote 2) ≡ ’2 is a boxed constant integer (but 2 is a constant long thing)
  - (quote "ab") ≡ "ab" is a boxed constant string
  - (quote x) ≡ ’x is a constant symbol (instance of class_symbol)

quote in Melt is different than quote in Lisp or Scheme. In Melt it makes constant boxed values, so ’2 ≠ 2
defining your mode and pass in Melt

code by Pierre Vittet in his GMWarn extension

\begin{verbatim}
(defun test_fopen_docmd (cmd moduldata)
  (let ((test_fopen ;; a local binding!
             (instance class_gcc_gimple_pass
                 :named_name "melt_test_fopen"
                 :gccpass_gate test_fopen_gate
                 :gccpass_exec test_fopen_exec
                 :gccpass_data (make_maptree descr_map_trees 1000)
                 :gccpass_properties_required ()
             ))) ;; body of the let follows:
    (install_melt_gcc_pass test_fopen "after" "ssa" 0)
    (debug_msg test_fopen "test_fopen_mode installed test_fopen")
    ;; return the pass to accept the mode
    (return test_fopen))

(definstance test_fopen class_melt_mode
    :named_name "test_fopen"
    :meltmode_help "monitor that after each call to fopen, there is a test"
    :meltmode_fun test_fopen_docmd
)
(install_melt_mode test_fopen)
\end{verbatim}
Handling GCC Internal Data with MELT

A central front-end and middle-end representation in GCC: in C the type `tree` (a pointer)

See files `$GCCSOURCE/gcc/tree.{def,h,c}`, and also `$GCCSOURCE/gcc/c-family/c-common.def` and other front-end dependent files. `#include`-`d from `$GCCBUILD/gcc/all-tree.def`

`tree.def` contains $\approx 190$ definitions like

```c
/* Contents are in TREE_INT_CST_LOW and TREE_INT_CST_HIGH fields, 32 bits each, giving us a 64 bit constant capability. INTEGER_CST nodes can be shared, and therefore should be considered read only. They should be copied, before setting a flag such as TREE_OVERFLOW. If an INTEGER_CST has TREE_OVERFLOW already set, it is known to be unique. INTEGER_CST nodes are created for the integral types, for pointer types and for vector and float types in some circumstances. */
DEFTREECODE (INTEGER_CST, "integer_cst", tcc_constant, 0)
```

Or

```c
/* C’s float and double. Different floating types are distinguished by machine mode and by the TYPE_SIZE and the TYPE_PRECISION. */
DEFTREECODE (REAL_TYPE, "real_type", tcc_type, 0)
```
Tree representation in C

tree.h contains

```c
struct GTY(()) tree_base {
    ENUM_BITFIELD(tree_code) code : 16;
    unsigned side_effects_flag : 1;
    unsigned constant_flag : 1;
    // many other flags
};
struct GTY(()) tree_typed {
    struct tree_base base;
    tree type;
};
// etc
union GTY ((ptr_alias (union lang_tree_node),
    desc ("tree_node_structure (&%h)", variable_size)) tree_node {
    struct tree_base GTY ((tag ("TS_BASE"))) base;
    struct tree_typed GTY ((tag ("TS_TYPED"))) typed;
    // many other cases
    struct tree_target_option GTY ((tag ("TS_TARGET_OPTION"))) target_option;
};
```

But $GCCSOURCE/gcc/coretypes.h has

typedef union tree_node *tree;
Gcc **Gimple-s**

**Gimple-s** represents instructions in Gcc in C the type **gimple** (a pointer)

See files `$GCCSOURCE/gcc/gimple.{def,h,c}`

`gimple.def` contains **36** definitions (**14** are for OpenMP !) like

```c
/* GIMPLE_GOTO <TARGET> represents unconditional jumps.
   TARGET is a LABEL_DECL or an expression node for computed GOTOs. */
DEFGSCODE(GIMPLE_GOTO, "gimple_goto", GSS_WITH_OPS)
```

Or

```c
/* GIMPLE_CALL <FN, LHS, ARG1, ..., ARGN[, CHAIN]> represents function calls.
   FN is the callee. It must be accepted by is_gimple_call_addr.
   LHS is the operand where the return value from FN is stored. It may be NULL.
   ARG1 ... ARGN are the arguments. They must all be accepted by is_gimple_operand.
   CHAIN is the optional static chain link for nested functions. */
DEFGSCODE(GIMPLE_CALL, "gimple_call", GSS_CALL)
```
/* GIMPLE_ASSIGN <SUBCODE, LHS, RHS1[, RHS2]> represents the assignment statement 
LHS = RHS1 SUBCODE RHS2.
SUBCODE is the tree code for the expression computed by the RHS of the assignment. It must be one of the tree codes accepted by get_gimple_rhs_class. If LHS is not a gimple register according to is_gimple_reg, SUBCODE must be of class GIMPLE_SINGLE_RHS.
LHS is the operand on the LHS of the assignment. It must be a tree node accepted by is_gimple_lvalue.
RHS1 is the first operand on the RHS of the assignment. It must always be present. It must be a tree node accepted by is_gimple_val.
RHS2 is the second operand on the RHS of the assignment. It must be a node accepted by is_gimple_val. This argument exists only if SUBCODE is of class GIMPLE_BINARY_RHS. */

DEFGSCODE(GIMPLE_ASSIGN, "gimple_assign", GSS_WITH_MEM_OPS)

Gimple operands are Tree-s. For Gimple/SSA, the Tree is often a SSA_NAME
**Gimple data in C**

in `$GCCSOURCE/gcc/gimple.h`:

```c
/* Data structure definitions for GIMPLE tuples. NOTE: word markers are for 64 bit hosts. */
struct GTY(()) gimple_statement_base {
    /* [ WORD 1 ] Main identifying code for a tuple. */
    ENUM_BITFIELD(gimple_code) code : 8;
    // etc...
    /* Number of operands in this tuple. */
    unsigned num_ops;
    /* [ WORD 3 ] Basic block holding this statement. */
    struct basic_block_def *bb;
    /* [ WORD 4 ] Lexical block holding this statement. */
    tree block;
};
/* Base structure for tuples with operands. */
struct GTY(()) gimple_statement_with_ops_base {
    /* [ WORD 1-4 ] */
    struct gimple_statement_base gsbase;
    /* [ WORD 5-6 ] SSA operand vectors. NOTE: It should be possible to amalgamate these vectors with the operand vector OP. However, the SSA operand vectors are organized differently and contain more information (like immediate use chaining). */
    struct def_optype_d GTY((skip (""))) *def_ops;
    struct use_optype_d GTY((skip (""))) *use_ops;
};
```

Basile Starynkevitch, Pierre Vittet

GCC plugins and MELT extensions (e.g. Talpo)

August 24th 2011

GHM’11 ⋆ 48 / 85
inline accessors to Gimple

gimple.h also have many inline functions, like e.g.

/* Return the code for GIMPLE statement G. crash if G is null */
static inline enum gimple_code gimple_code (const_gimple g) {...}

/* Set the UID of statement. data for inside passes */
static inline void gimple_set_uid (gimple g, unsigned uid) {...}

/* Return the UID of statement. */
static inline unsigned gimple_uid (const_gimple g) {...}

/* Return true if GIMPLE statement G has register or memory operands. */
static inline bool gimple_has_ops (const_gimple g) {...}

/* Return the set of DEF operands for statement G. */
static inline struct def_optype_d *gimple_def_ops (const_gimple g) {...}

/* Return operand I for statement GS. */
static inline tree gimple_op (const_gimple gs, unsigned i) {...}

/* If a given GIMPLE_CALL’s callee is a FUNCTION_DECL, return it.
Otherwise return NULL. This function is analogous to get_callee_fndecl in tree
*/
static inline tree gimple_call_fndecl (const_gimple gs) {...}

/* Return the LHS of call statement GS. */
static inline tree gimple_call_lhs (const_gimple gs) {...}

There are also functions to build or modify gimple
control-flow related representations inside Gcc

- **gimple** are simple instructions
- **gimple_seq** are sequence of **gimple-s**
- **basic_block** are elementary blocks, containing a **gimple_seq** and connected to other basic blocks thru **edge-s**
- **edge-s** connect basic blocks (i.e. are jumps!)
- **loop-s** are for dealing with loops, knowing their basic block **headers** and **latches**
- the struct **control_flow_graph** packs entry and exit blocks and a vector of basic blocks for a function
- the struct **function** packs the **control_flow_graph** and the **gimple_seq** of the function body, etc . . .
- **loop-s** are hierachically organized inside the struct **loops** (e.g. the **current_loops** global) for the current function.

NB: **not every representation is available** in every pass!
Basic Blocks in Gcc

coretypes.h has typedef struct basic_block_def *basic_block;

In $GCCSOURCE/gcc/basic-block.h

/* Basic block information indexed by block number. */
struct GTY(((chain_next ("%h.next_bb"), chain_prev("%h.prev_bb"))) basic_block_def
    /* The edges into and out of the block. */
    VEC(edge,gc) *preds;
    VEC(edge,gc) *succs;  //etc...
    /* Innermost loop containing the block. */
    struct loop *loop_father;
    /* The dominance and postdominance information node. */
    struct et_node * GTY ((skip (""))) dom[2];
    /* Previous and next blocks in the chain. */
    struct basic_block_def *prev_bb;
    struct basic_block_def *next_bb;
union basic_block_il_dependent {
    struct gimple_bb_info * GTY ((tag ("0"))) gimple;
    struct rtl_bb_info * GTY ((tag ("1"))) rtl;
} GTY ((desc ("((%1.flags & BB_RTL) != 0)"))) il;
// etc ....
/* Various flags. See BB_* below. */
int flags;
};
gimple_bb_info & control_flow_graph

Also in basic-block.h

```c
struct GTY() gimple_bb_info {
    /* Sequence of statements in this block. */
    gimple_seq seq;
    /* PHI nodes for this block. */
    gimple_seq phi_nodes;
};

/* A structure to group all the per-function control flow graph data. */
struct GTY() control_flow_graph {
    /* Block pointers for the exit and entry of a function. 
       These are always the head and tail of the basic block list. */
    basic_block x_entry_block_ptr;
    basic_block x_exit_block_ptr;
    /* Index by basic block number, get basic block struct info. */
    VEC(basic_block,gc) *x_basic_block_info;
    /* Number of basic blocks in this flow graph. */
    int x_n_basic_blocks;
    /* Number of edges in this flow graph. */
    int x_n_edges;
    // etc ...
};
```
Control Flow Graph and loop-s in Gcc

In $GCCSOURCE/gcc/cfgloop.h

```c
/* Description of the loop exit. */
struct
GTY (()) loop_exit {
    /* The exit edge. */
    struct edge_def *e;
    /* Previous and next exit in the list of the exits of the loop. */
    struct loop_exit *prev; struct loop_exit *next;
    /* Next element in the list of loops from that E exits. */
    struct loop_exit *next_e; }

typedef struct loop *loop_p;

/* Structure to hold information for each natural loop. */
struct
GTY ((chain_next ("%h.next"))) loop {
    /* Index into loops array. */
    int num;
    /* Number of loop insns. */
    unsigned ninsns;
    /* Basic block of loop header. */
    struct basic_block_def *header;
    /* Basic block of loop latch. */
    struct basic_block_def *latch;
    // etc ...
    /* True if the loop can be parallel. */
    bool can_be_parallel;
    /* Head of the cyclic list of the exits of the loop. */
    struct loop_exit *exits;
}
```
Caveats on GCC internal representations

- In principle, **they are not stable** (could change in 4.7 or next)
- In practice, **changing central representations** (like gimple or tree) is very **difficult**:  
  - GCC gurus (and users?) care about compilation time  
  - GCC people could “fight” for some bits  
  - Changing them is very costly: ⇒ need to patch every pass  
  - You need to convince the whole GCC community to enhance them  
  - Some GCC heroes could change them

- **Extensions or plugins cannot add extra data fields** (into tree-s, gimple-s\(^{25}\) or basic_block-s, …)  
  ⇒ Use other data (e.g. associative hash tables) to link your data to them

\(^{25}\)Gimple-s have uid-s but they are only for inside passes!
Handling GCC stuff with MELT

GCC raw stuff is handled by Melt c-types like :gimple_seq or :edge

- raw stuff can be passed as formal arguments or given as secondary results
- Melt functions
  - first argument should be a value
  - first result is a value
- raw stuff have boxed values counterpart
- raw stuff have hash-maps values (to associate a non-nil Melt value to a tree, a gimple etc)
- primitive operations can handle stuff or values
- c-iterators can iterate inside stuff or values

---

26 i.e. the receiver, when sending a message in Melt
Primitives in Melt

Primitive operations have arbitrary (but fixed) signature, and give one result (which could be `void`).

used e.g. in Melt where `body` is some `basic_block` stuff
(code by Jérémie Salvucci from `xtramelt-c-generator.melt`)

```melt
(let ( (:gimple_seq instructions (gimple_seq_of_basic_block body)) )
  ;; do something with instructions
)
```

(gimple_seq_of_basic_block takes a `basic_block` stuff & gives a `gimple_seq` stuff)

Primitives are defined thru `defprimitive` by macro-strings, e.g. in

```
$GCCMELTSOURCE/gcc/melt/xtramelt-ana-base.melt
```

```melt
(defprimitive gimple_seq_of_basic_block (:basic_block bb) :gimple_seq
  #{($BB)?bb_seq(($BB)):NULL})#
```

(always test for 0 or null, since Melt data is cleared initially)

Likewise, arithmetic on raw `long` stuff is defined (in `warmelt-first.melt`):

```melt
(defprimitive +i (:long a b) :long
  :doc #{Integer binary addition of $a and $b.}#
  #{(($A) + ($B))}#)
```

(no boxed arithmetic primitive yet in Melt)
c-iterators in Melt

C-iterators describe how to iterate, by generation of for-like constructs, with

- **input** arguments - for parameterizing the iteration
- **local** formals - giving locals changing on each iteration

So if \( bb \) is some Melt :basic_block stuff, we can iterate on its contained :gimple-s using

```c
(eachgimple_in_basicblock
  (bb) ;; input arguments
  (:gimple g) ;; local formals
  (debuggimple "our g" g) ;; do something with g
)
```

The definition of a c-iterator, in a defciterator, uses a state symbol (like in code_chunk-s) and two “before” and “after” macro-strings, expanded in the head and the tail of the generated C loop.
Example of `defciterator`

```melt
(defciterator eachgimple_in_basicblock
  (:basic_block bb) ; start formals
  eachgimpbb ; state symbol
  (:gimple g) ; local formals
  ;; before expansion
  #{{ /* start $EACHGIMPBB */
    gimple_stmt_iterator gsi_$EACHGIMPBB;
    if ($BB)
      for (gsi_eachgimpbb = gsi_start_bb ($BB);
        !gsi_end_p (gsi_$EACHGIMPBB);
        gsi_next (&gsi_$EACHGIMPBB))
      {
        $G = gsi_stmt (gsi_$EACHGIMPBB);  
      }
  }#
  ;; after expansion
  #{{ }/* end $EACHGIMPBB */ }#
)
```

(most iterations in Gcc fit into c-iterators; because few are callbacks based)
values in Melt

Each value starts with an immutable [often predefined] **discriminant** (for a Melt object value, the discriminant is its class).

---

Melt copying generational garbage collector manages [only] values (it copies live Melt values into Ggc heap).
values taxonomy

- classical almost Scheme-like (or Python-like) values:
  1. the **nil** value ( ) - it is the only **false** value (unlike Scheme)
  2. **boxed integers**, e.g. ’2; or **boxed strings**, e.g. ’"ab"
  3. **symbols** (objects of class_symbol), e.g. ’x
  4. **closures**, i.e. functions [only values can be closed by `lambda` or `defun`]
     (also [internal to closures] routines containing constants)
     e.g. `(lambda (f :tree t) (f y t))` has closed y
  5. **pairs** (rarely used alone)

- **boxed stuff**, e.g. **boxed gimples** or **boxed basic blocks**, etc …

- **lists** of pairs (unlike Scheme, they know their first and last pairs)

- **tuples** ≡ fixed array of immutable components

- **associative homogenous hash-maps**, keyed by either
  - non-nil Gcc raw stuff like :tree-s, :gimple-s … (all keys of same type), or
  - Melt objects

  with each such key associated to a non-nil Melt value

- **objects** - (their discriminant is their class)
lattice of discriminants

- Each value has its immutable discriminant.
- Every discriminant is an object of `class_discriminant` (or a subclass)
- Classes are objects of `class_class`
  Their fields are reified as instances of `class_field`
- The nil value (represented by the `NULL` pointer in generated C code) has `discr_null_reciever` as its discriminant.
- Each discriminant has a parent discriminant (the super-class for classes)
- The top-most discriminant is `discr_any_reciever` (usable for catch-all methods)
- Discriminants are used by garbage collectors (both Melt and Ggc!)
- Discriminants are used for Melt message sending:
  - Each message send has a selector $\sigma$ & a reciever $\rho$, i.e. $(\sigma \ \rho \ ...)$
  - Selectors are objects of `class_selector` defined with `defselector`
  - Recievers can be any Melt value (even nil)
  - Discriminants have a `:disc_methodict` field - an object-map associating selectors to methods (closures); and their `:disc_super`
C-type example: **ctype_tree**

Our c-types are described by Melt [predefined] objects, e.g.

```c
;; the C type for gcc trees
definstance ctype_tree class_c_type_gty
  :doc #{The $CTYPE_TREE is the c-type of raw GCC tree stuff. See also $DISCR_TREE. Keyword is :tree.}#
  :predef CTYPE_TREE
  :named_name "CTYPE_TREE"
  :ctype_keyword :tree
  :ctype_cname "tree"
  :ctype_parchar "MELTBPAR_TREE"
  :ctype_parstring "MELTBPARSTR_TREE"
  :ctype_argfield "meltbp_tree"
  :ctype_resfield "meltbp_treeptr"
  :ctype_marker "gt_ggc_mx_tree_node"

;; GTY ctype
  :ctypg_boxedmagic "MELTOBMAG_TREE"
  :ctypg_mapmagic "MELTOBMAG_MAPTREES"
  :ctypg_boxedstruct "melttree_st"
  :ctypg_boxedunimemb "u_tree"
  :ctypg_entrystruct "entrytreemelt_st"
  :ctypg_mapstruct "meltmaptrees_st"
  :ctypg_boxdiscr discr_tree
  :ctypg_mapdiscr discr_map_trees
  :ctypg_mapunimemb "u_maptrees"
  :ctypg_boxfun
  :ctypg_unboxfun
  :ctypg_updateboxfun
  :ctypg_newmapfun
  :ctypg_mapgetfun
  :ctypg_mapputfun
  :ctypg_mapremovefun
  :ctypg_mapsizefun
  :ctypg_mapcountfun
  :ctypg_mapnattfun
  :ctypg_mapnvalfun

(install_ctype_descr
  ctype_tree "GCC tree pointer")
```

The strings are the names of **generated run-time support** routines (or types, enum-s, fields ...) in `$GCCMELTSOURCE/gcc/melt/generated/meltrunsup*.ch`
Melt objects and classes

Melt objects have a single class (class hierarchy rooted at \texttt{class\_root})

Example of class definition in \texttt{warmelt-debug.melt}:

```melt
;; class for debug information (used for debug\_msg & dbgout* stuff)
(defclass class\_debug\_information
 :super class\_root
 :fields (dbgi\_out dbgi\_occmap dbgi\_maxdepth)
 :doc #{The \$CLASS\_DEBUG\_INFORMATION is for debug information output, e.g. \$DEBUG\_MSG macro. The produced output or buffer is \$DBGI\_OUT, the occurrence map is \$DBGI\_OCCMAP, used to avoid outputting twice the same object. The boxed maximal depth is \$DBGI\_MAXDEPTH.}#}
)

We use it in code like

```melt
(let ((dbgi (instance class\_debug\_information
   :dbgi\_out out
   :dbgi\_occmap occmap
   :dbgi\_maxdepth boxedmaxdepth))
   (:long framdepth (the\_framedepth)))
  (add2out\_strconst out "!!!!*****####")
  ;; etc)
```
Melt fields and objects

Melt field names are globally unique

- \( \Rightarrow (\text{get\_field} : \text{dbgi\_out} \ \text{dbgi}) \) is translated to safe code:
  1. testing that indeed \( \text{dbgi} \) is instance of \text{class\_debug\_information}, then
  2. extracting its \( \text{dbgi\_out} \) field.

- (\( \Rightarrow \) never use \text{unsafe\_get\_field}, or your code could crash)
- Likewise, \text{put\_fields} is safe
- (\( \Rightarrow \) never use \text{unsafe\_put\_fields})
- convention: all proper field names of a class share a common prefix
- no visibility restriction on fields
  (except module-wise, on “private” classes not passed to \text{export\_class})

Classes are conventionally named \text{class}\_*

Methods are dynamically installable on any discriminant, using
\( \text{(install\_method} \ \text{discriminant} \ \text{selector} \ \text{method}) \)
About pattern matching

You already used it, e.g.

- in regular expressions for substitution with `sed`
- in XSLT or Prolog (or expert systems rules with variables, or formal symbolic computing)
- in Ocaml, Haskell, Scala

A tiny calculator in Ocaml:

```ocaml
(*discriminated unions [sum type], with cartesian products*)
type expr_t = Num of int |
              Add of expr_t * expr_t |
              Mul of expr_t * expr_t ;;

(*recursively compute an expression thru pattern matching*)
let rec compute e = match e with
  Num x  →  x
| Add (a,b) →  a + b
(*disjunctive pattern with joker _ and constant sub-patterns::*)
| Mul (_,Num 0) | Mul (Num 0,_) →  0
| Mul (a,b)    →  a * b ;;
(*inferred type: compute : expr_t → int *)

Then compute (Add (Num 1, Mul (Num 2, Num 3))) ⇒ 7
```
Using pattern matching in your Melt code

code by Pierre Vittet

(defun detect_cond_with_null (grdata :gimple g)
  (match g ;; the matched thing
    ( ?(gimple_cond_notequal ?lhs
        ?(tree_integer_cst 0))
      (make_tree descr_tree lhs))
    ( ?(gimple_cond_equal ?lhs
        ?(tree_integer_cst 0))
      (make_tree descr_tree lhs))
    ( ?
      (make_tree descr_tree (null_tree)))))

- lexical shortcut: \( ?\pi \equiv (\text{question } \pi) \), much like \( '\epsilon \equiv (\text{quote } \epsilon) \)
- patterns are major syntactic constructs (like expressions or bindings are; parsed with pattern macros or “patmacros”), first in matching clauses
- \(?_\) is the joker pattern, and \(?\text{lhs}\) is a pattern variable (local to its clause)
- most patterns are nested, made with matchers, e.g. \(\text{gimple_cond_notequal}\) or \(\text{tree_integer_cst}\)
What \texttt{match} does?

\begin{itemize}
\item Syntax is \texttt{(match } \epsilon \texttt{ } \kappa_1 \ldots \kappa_n \texttt{ )} with \( \epsilon \) an expression giving \( \mu \) and \( \kappa_j \) are matching clauses considered in sequence.
\item The \texttt{match} expression returns a result (some thing, perhaps :\texttt{void})
\item It is made of matching clauses \( ( \pi_i \ \epsilon_{i,1} \ldots \epsilon_{i,n_i} \ \eta_i ) \), each starting with a pattern\(^{27} \pi_i \) followed by sub-expressions \( \epsilon_{i,j} \) ending with \( \eta_i \)
\item It matches (or filters) some thing \( \mu \)
\item Pattern variables are \texttt{local} to their clause, and \texttt{initially cleared}
\item When pattern \( \pi_i \) matches \( \mu \) the expressions \( \epsilon_{i,j} \) of clause \( i \) are executed in sequence, with the pattern variables inside \( \pi_i \) locally bound. The last sub-expression \( \eta_i \) of the match clause gives the result of the entire \texttt{match} (and all \( \eta_i \) should have a common c-type, or else :\texttt{void})
\item If no clause matches -this is bad taste, usually last clause has the ?_joker pattern-, the result is cleared
\item A pattern \( \pi_i \) can \texttt{match} the thing \( \mu \) or \texttt{fail}
\end{itemize}

\(^{27}\) Expressions, e.g. constant litterals, are degenerate patterns!
pattern matching rules

rules for matching of pattern $\pi$ against thing $\mu$:

- the **joker pattern** $?_x$ always match
- an **expression** (e.g. a constant) $\epsilon$ (giving $\mu'$) matches $\mu$ iff ($\mu' == \mu$) in C parlance
- a **pattern variable** like $?x$ matches if
  - $x$ was unbound; then it is **bound** (locally to the clause) to $\mu$
  - or else $x$ was already bound to some $\mu'$ and ($\mu' == \mu$) [non-linear patterns]
  - otherwise ($x$ was bound to a different thing), the pattern variable $?x$ match fails
- a **matcher pattern** $?(m \ \eta_1 \ldots \eta_n \ \pi'_1 \ldots \pi'_p)$ with $n \geq 0$ input argument sub-expressions $\eta_i$ and $p \geq 0$ sub-patterns $\pi'_j$
  - the matcher $m$ does a **test** using results $\rho_i$ of $\eta_i$
  - if the test succeeds, data are extracted in the fill step and each should match its $\pi'_j$
  - otherwise (the test fails, so) the match fails
- an **instance pattern** $?(\text{instance } \kappa : \phi_1 \ \pi'_1 \ldots : \phi_n \ \pi'_n)$ matches iff $\mu$ is an object of class $\kappa$ (or a sub-class) with each field $\phi_i$ matching its sub-pattern $\pi'_i$
control patterns

We have controlling patterns

- **conjonctive pattern** \(? \text{and } \pi_1 \ldots \pi_n\) matches \(\mu\) iff \(\pi_1\) matches \(\mu\) and then \(\pi_2\) matches \(\mu\) 

- **disjonctive pattern** \(? \text{or } \pi_1 \ldots \pi_n\) matches \(\mu\) iff \(\pi_1\) matches \(\mu\) or else \(\pi_2\) matches \(\mu\)

Pattern variables are initially cleared, so \((\text{match } 1 (\text{?(or ?x ?y) y}))\) gives 0 (as a :long stuff)

(other control patterns would be nice, e.g. backtracking patterns)
Two kinds of matchers:

1. **c-matchers** giving the *test* and the *fill* code thru expanded macro-strings
   
   ```lisp
   (defcmatcher gimple_cond_equal
     (:gimple gc) ;; matched thing µ
     (:tree lhs :tree rhs) ;; subpatterns putput
     gce ;; state symbol
     ;; test expansion:
     #{($GC &&
       gimple_code ($GC) == GIMPLE_COND &&
       gimple_cond_code ($GC) == EQ_EXPR)
       #}
     ;; fill expansion:
     #{ $LHS = gimple_cond_lhs ($GC);
       $RHS = gimple_cond_rhs ($GC);
     }#)
   
   2. **fun-matchers** give test and fill steps thru a Melt function returning secondary results

Basile Starynkevitch, Pierre Vittet

GCC plugins and MELT extensions (e.g. Talpo)

August 24\textsuperscript{th} 2011 \textit{GHM'11}
known MELT weaknesses [corrections are worked upon]

1. pattern matching translation is weak\(^{28}\)
   (a new pattern translator is nearly completed)

2. **Melt** passes can be slow
   - better and faster **Melt** application
   - memoization in message sends
   - optimization of **Melt** G-C invocations and **Ggc** invocations

3. variadic functions (e.g. debug printing)

4. dump support

5. debug support
   - plugins want their **gcc** with `-enable-check=all`, not `-enable-check=release`
   - **Melt** debug\(_\text{msg}\) wants `-fmelt-debug` and `-enable-check=...`
   - a probing process?

\(^{28}\) Sometimes crashing the **Melt** translator 😞
1 Introduction
- about you and me
- about GCC and MELT
- running GCC

2 MELT
- why MELT?
- handling GCC internal data with MELT
- matching GCC data with MELT
- future work on MELT

3 Talpo
- Foreword about Talpo
- Type of tests
- Using Talpo
- Modularity

4 Conclusion
Talpo means mole in Esperanto!

The idea of the name is that it digs blindly into GCC (without knowing much where it goes :) ) and calls still found useful informations you need.

In fact: a customizable GCC extension (written in MELT) to run simple analysis in your C/C++ programs.

Use case:

- You want to check that a call to `malloc` function is followed by a call to `free` in the same function.
- You want to check that a call to `fopen` is immediately followed by a test on his returned pointer.
- Checking that there is (or not) code after an `execX*` (execl, execlp, execle, execv, execvp, execvpe) (to check for error for example).
**Talpo** started with the idea that a static analysis tool can use the powerful functionalities of **GCC** and must be customized for a project: A **Talpo** test can be easily parameterized by people ignoring (much of) **GCC** and **MELT**. With Talpo you can check this:

- for each call to a foo function, result of the call is tested to be (not) NULL/negative/zero.
- each call to a foo function is immediately followed by a call to a bar function.
- each call to a foo function is followed by a call to a bar function in the same function body.

This is quite simple and limited but can already be useful in many cases!

---

29 https://gitorious.org/talpo
Easy to use

There are different ways to pass argument to Talpo:

Using pragma in code file

```c
#pragma MELT talpo testNull(fopen)
#pragma MELT talpo test_followed\by(chroot, chdir)
```

Using direct argument

```c
gcc ... 
-fplugin -arg=melt -option=talpo -arg='(testNull "fopen")\(test_followed_by "chroot" "chown"\)'
...
```

Using a file to list argument

```c
-fplugin -arg=melt -option=talpo -arg=file ='myfile'
```
You can easily implement a new way to read user input.
You can easily implement a new test.
Try it!

C code

```c
#include <stdio.h>
int main(void){
    FILE * test;
    test=fopen("test","a");
    return 0;
}
```

Result

```bash
gcc -Wall -fplugin=melt -fplugin-arg=melt -mode=talpo \ 
-fplugin-arg=melt -module-path=${(talpoPath)} \ 
-fplugin-arg=melt -source-path=. \ 
-fplugin-arg=melt -extra=@$({talpoPath})/talpo \ 
-fplugin-arg=melt -option=talpo-arg='(testNull "fopen")' \ 
-O2 test.c -o test.o
```

test_simple_check_cfile.c:5:10: warning: Melt Warning[#221]: Function 'fopen' \ 
not followed by a test on his returned pointer.
Using post-dominating basicblock

C code

```c
int main(void) {
    int i = 0;
    FILE * test;
    FILE * test2;
    if (i == 1)
        test = fopen("toto", "a");
    else
        test2 = fopen("tata", "a");
    if (test == NULL)
        return 1;
    return 0;
}
```

Result

test_simple_check_cfile.c:8:10: warning: Melt Warning[#216]: Function 'fopen' not followed by a test on his returned pointer.
Using a struct

C code

typedef struct _myStr
{
    FILE * ptrfile;
} myStr;

int use_struct_no_warn (void)
{
    myStr * testStr = (myStr *) malloc(sizeof(myStr));
    testStr->ptrfile=fopen("toto", "a");
    if (!testStr->ptrfile)
        return 1;
    return 0;
}

Result

(No warnings returned!)
On a different variable

C code

```c
int not_same_var_warn_once()
{
    char * curDir = (char *) malloc(sizeof(char) * 3);
    char * notCurDir = (char *) malloc(sizeof(char) * 3);
    curDir = ".";
    chroot(curDir);
    chdir(notCurDir);
    return 0;
}
```

Result

```
gcc -Wall -fplugin=melt -fplugin-arg=melt-mode=talpo \
-fplugin-arg=melt-module-path='$ (talpoPath)' \
-fplugin-arg=melt-source-path=.. \
-fplugin-arg=melt-extra= @$ (talpoPath)/talpo \
-fplugin-arg=melt-option=talpo-arg='(testFollowedBy_"chroot"_1_"chdir"_1) ' \
-O2 test.c -o test.o
```

test.c:8:4: attention : Melt Warning[#254]: Call to 'chroot' is not followed \ 
by a call to 'chdir'. [enabled by default]
What does not work

For some code samples, it still returns false positives.
Function pointer are not detected!

C code

```c
int main()
{
    FILE * (*myPtr)(char *, char *);  
    myPtr = fopen;

    FILE * res = myPtr("path","a");
    return 0;
}
```

Result
(No warnings returned!)
C++ code

The following case has been asked by Jonathan Wakely on the GCC mailing list:

```cpp
struct Guard {
    Guard(void* p) : p(p) { if (!p) throw std::bad_alloc(); }
    ~Guard() { grub_free(p); }
    void* p;
};

void func(grub_size_t n)
{
    Guard g(grub_malloc(n));
    // do something with g.p
}
```

Result

(No warnings returned with -O0!)

4. Conclusion
Free software is about adapting software to your needs: Plugins are a great way to customize Gcc.

Melt simplifies writing Gcc extensions (and is more fun than coding in C).

We invite you to test Talpo, code in MELT, extend them!

Manu projects could provide their specific MELT extensions to help their C coders: Hurd, MPC, MPFR, GTK, Qt...

30MELT also has a mailing list: gcc-melt@googlegroup.com
