1 Introduction

Automake is a tool for automatically generating `Makefile.ins` from files called `Makefile.am`. Each `Makefile.am` is basically a series of `make` variable definitions\(^1\), with rules being thrown in occasionally. The generated `Makefile.ins` are compliant with the GNU Makefile standards.

The GNU Makefile Standards Document (see Section “Makefile Conventions” in *The GNU Coding Standards*) is long, complicated, and subject to change. The goal of Automake is to remove the burden of Makefile maintenance from the back of the individual GNU maintainer (and put it on the back of the Automake maintainers).

The typical Automake input file is simply a series of variable definitions. Each such file is processed to create a `Makefile.in`. There should generally be one `Makefile.am` per directory of a project.

Automake does constrain a project in certain ways; for instance, it assumes that the project uses Autoconf (see Section “Introduction” in *The Autoconf Manual*), and enforces certain restrictions on the `configure.ac` contents\(^2\).

Automake requires `perl` in order to generate the `Makefile.ins`. However, the distributions created by Automake are fully GNU standards-compliant, and do not require `perl` in order to be built.

For more information on bug reports, See Section 28.12 [Reporting Bugs], page 146.

2 An Introduction to the Autotools

If you are new to Automake, maybe you know that it is part of a set of tools called *The Autotools*. Maybe you’ve already delved into a package full of files named `configure`, `configure.ac`, `Makefile.in`, `Makefile.am`, `aclocal.m4`, ..., some of them claiming to be generated by Autoconf or Automake. But the exact purpose of these files and their relations is probably fuzzy. The goal of this chapter is to introduce you to this machinery, to show you how it works and how powerful it is. If you’ve never installed or seen such a package, do not worry: this chapter will walk you through it.

If you need some teaching material, more illustrations, or a less `automake`-centered continuation, some slides for this introduction are available in Alexandre Duret-Lutz’s Autotools Tutorial (http://www.lrde.epita.fr/~adl/autotools.html). This chapter is the written version of the first part of his tutorial.

2.1 Introducing the GNU Build System

It is a truth universally acknowledged, that as a developer in possession of a new package, you must be in want of a build system.

---

\(^1\) These variables are also called *make macros* in Make terminology, however in this manual we reserve the term *macro* for Autoconf’s macros.

\(^2\) Older Autoconf versions used `configure.in`. Autoconf 2.50 and greater promotes `configure.ac` over `configure.in`. The rest of this documentation will refer to `configure.ac`, but Automake also supports `configure.in` for backward compatibility.
In the Unix world, such a build system is traditionally achieved using the command `make` (see Section “Overview” in The GNU Make Manual). You express the recipe to build your package in a `Makefile`. This file is a set of rules to build the files in the package. For instance the program `prog` may be built by running the linker on the files `main.o`, `foo.o`, and `bar.o`; the file `main.o` may be built by running the compiler on `main.c`; etc. Each time `make` is run, it reads `Makefile`, checks the existence and modification time of the files mentioned, decides what files need to be built (or rebuilt), and runs the associated commands.

When a package needs to be built on a different platform than the one it was developed on, its `Makefile` usually needs to be adjusted. For instance the compiler may have another name or require more options. In 1991, David J. MacKenzie got tired of customizing `Makefile` for the 20 platforms he had to deal with. Instead, he handcrafted a little shell script called `configure` to automatically adjust the `Makefile` (see Section “Genesis” in The Autoconf Manual). Compiling his package was now as simple as running `./configure && make`.

Today this process has been standardized in the GNU project. The GNU Coding Standards (see Section “Managing Releases” in The GNU Coding Standards) explains how each package of the GNU project should have a `configure` script, and the minimal interface it should have. The `Makefile` too should follow some established conventions. The result? A unified build system that makes all packages almost indistinguishable by the installer. In its simplest scenario, all the installer has to do is to unpack the package, run `./configure && make && make install`, and repeat with the next package to install.

We call this build system the GNU Build System, since it was grown out of the GNU project. However it is used by a vast number of other packages: following any existing convention has its advantages.

The Autotools are tools that will create a GNU Build System for your package. Autoconf mostly focuses on `configure` and Automake on `Makefiles`. It is entirely possible to create a GNU Build System without the help of these tools. However it is rather burdensome and error-prone. We will discuss this again after some illustration of the GNU Build System in action.

### 2.2 Use Cases for the GNU Build System

In this section we explore several use cases for the GNU Build System. You can replay all these examples on the `amhello-1.0.tar.gz` package distributed with Automake. If Automake is installed on your system, you should find a copy of this file in `prefix/share/doc/automake/amhello-1.0.tar.gz`, where `prefix` is the installation prefix specified during configuration (`prefix` defaults to `/usr/local`, however if Automake was installed by some GNU/Linux distribution it most likely has been set to `/usr`). If you do not have a copy of Automake installed, you can find a copy of this file inside the `doc/` directory of the Automake package.

Some of the following use cases present features that are in fact extensions to the GNU Build System. Read: they are not specified by the GNU Coding Standards, but they are nonetheless part of the build system created by the Autotools. To keep things simple, we do not point out the difference. Our objective is to show you many of the features that the build system created by the Autotools will offer to you.
2.2.1 Basic Installation

The most common installation procedure looks as follows.

```
~ % tar zxf amhello-1.0.tar.gz
~ % cd amhello-1.0
~/amhello-1.0 % ./configure
...
config.status: creating Makefile
config.status: creating src/Makefile
...
~/amhello-1.0 % make
...
~/amhello-1.0 % make check
...
~/amhello-1.0 % su
Password:
/home/adl/amhello-1.0 # make install
...
/home/adl/amhello-1.0 # exit
~/amhello-1.0 % make installcheck
...
```

The user first unpacks the package. Here, and in the following examples, we will use the non-portable `tar zxf` command for simplicity. On a system without GNU `tar` installed, this command should read `gunzip -c amhello-1.0.tar.gz | tar xf -`.

The user then enters the newly created directory to run the `configure` script. This script probes the system for various features, and finally creates the Makefiles. In this toy example there are only two Makefiles, but in real-world projects, there may be many more, usually one `Makefile` per directory.

It is now possible to run `make`. This will construct all the programs, libraries, and scripts that need to be constructed for the package. In our example, this compiles the `hello` program. All files are constructed in place, in the source tree; we will see later how this can be changed.

`make check` causes the package’s tests to be run. This step is not mandatory, but it is often good to make sure the programs that have been built behave as they should, before you decide to install them. Our example does not contain any tests, so running `make check` is a no-op.

After everything has been built, and maybe tested, it is time to install it on the system. That means copying the programs, libraries, header files, scripts, and other data files from the source directory to their final destination on the system. The command `make install` will do that. However, by default everything will be installed in subdirectories of `/usr/local`: binaries will go into `/usr/local/bin`, libraries will end up in `/usr/local/lib`, etc. This destination is usually not writable by any user, so we assume that we have to become root before we can run `make install`. In our example, running `make install` will copy the program `hello` into `/usr/local/bin` and README into `/usr/local/share/doc/amhello`. 
A last and optional step is to run **make installcheck**. This command may run tests on the installed files. **make check** tests the files in the source tree, while **make installcheck** tests their installed copies. The tests run by the latter can be different from those run by the former. For instance, there are tests that cannot be run in the source tree. Conversely, some packages are set up so that **make installcheck** will run the very same tests as **make check**, only on different files (non-installed vs. installed). It can make a difference, for instance when the source tree’s layout is different from that of the installation. Furthermore it may help to diagnose an incomplete installation.

Presently most packages do not have any **installcheck** tests because the existence of **installcheck** is little known, and its usefulness is neglected. Our little toy package is no better: **make installcheck** does nothing.

### 2.2.2 Standard Makefile Targets

So far we have come across four ways to run **make** in the GNU Build System: **make**, **make check**, **make install**, and **make installcheck**. The words **check**, **install**, and **installcheck**, passed as arguments to **make**, are called **targets**. **make** is a shorthand for **make all**, **all** being the default target in the GNU Build System.

Here is a list of the most useful targets that the GNU Coding Standards specify.

- **make all**  Build programs, libraries, documentation, etc. (same as **make**).
- **make install**  Install what needs to be installed, copying the files from the package’s tree to system-wide directories.
- **make install-strip**  Same as **make install**, then strip debugging symbols. Some users like to trade space for useful bug reports...  
- **make uninstall**  The opposite of **make install**: erase the installed files. (This needs to be run from the same build tree that was installed.)
- **make clean**  Erase from the build tree the files built by **make all**.
- **make distclean**  Additionally erase anything **./configure** created.
- **make check**  Run the test suite, if any.
- **make installcheck**  Check the installed programs or libraries, if supported.
- **make dist**  Recreate **package-version.tar.gz** from all the source files.

### 2.2.3 Standard Directory Variables

The GNU Coding Standards also specify a hierarchy of variables to denote installation directories. Some of these are:
Chapter 2: An Introduction to the Autotools

<table>
<thead>
<tr>
<th>Directory variable</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>/usr/local</td>
</tr>
<tr>
<td>exec_prefix</td>
<td>${prefix}</td>
</tr>
<tr>
<td>bindir</td>
<td>${exec_prefix}/bin</td>
</tr>
<tr>
<td>libdir</td>
<td>${exec_prefix}/lib</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>includedir</td>
<td>${prefix}/include</td>
</tr>
<tr>
<td>datarootdir</td>
<td>${prefix}/share</td>
</tr>
<tr>
<td>datadir</td>
<td>${datarootdir}</td>
</tr>
<tr>
<td>mandir</td>
<td>${datarootdir}/man</td>
</tr>
<tr>
<td>infodir</td>
<td>${datarootdir}/info</td>
</tr>
<tr>
<td>docdir</td>
<td>${datarootdir}/doc/${PACKAGE}</td>
</tr>
</tbody>
</table>

Each of these directories has a role which is often obvious from its name. In a package, any installable file will be installed in one of these directories. For instance in amhello-1.0, the program hello is to be installed in bindir, the directory for binaries. The default value for this directory is /usr/local/bin, but the user can supply a different value when calling configure. Also the file README will be installed into docdir, which defaults to /usr/local/share/doc/amhello.

As a user, if you wish to install a package on your own account, you could proceed as follows:

```
~/amhello-1.0 % ./configure --prefix ~/usr
...
~/amhello-1.0 % make
...
~/amhello-1.0 % make install
...
```

This would install ~/usr/bin/hello and ~/usr/share/doc/amhello/README.

The list of all such directory options is shown by ./configure --help.

2.2.4 Standard Configuration Variables

The GNU Coding Standards also define a set of standard configuration variables used during the build. Here are some:

- **CC**  
  C compiler command
- **CFLAGS**  
  C compiler flags
- **CXX**  
  C++ compiler command
- **CXXFLAGS**  
  C++ compiler flags
- **LDFLAGS**  
  linker flags
- **CPPFLAGS**  
  C/C++ preprocessor flags

configure usually does a good job at setting appropriate values for these variables, but there are cases where you may want to override them. For instance you may have several
versions of a compiler installed and would like to use another one, you may have header files installed outside the default search path of the compiler, or even libraries out of the way of the linker.

Here is how one would call `configure` to force it to use `gcc-3` as C compiler, use header files from `~/.usr/include` when compiling, and libraries from `~/.usr/lib` when linking.

```
~/.amhello-1.0 % ./configure --prefix ~/.usr CC=gcc-3
CPPFLAGS=-I$HOME/usr/include LDFLAGS=-L$HOME/usr/lib
```

Again, a full list of these variables appears in the output of `./configure --help`.

### 2.2.5 Overriding Default Configuration Setting with `config.site`

When installing several packages using the same setup, it can be convenient to create a file to capture common settings. If a file named `prefix/share/config.site` exists, `configure` will source it at the beginning of its execution.

Recall the command from the previous section:

```
~/.amhello-1.0 % ./configure --prefix ~/.usr CC=gcc-3
CPPFLAGS=-I$HOME/usr/include LDFLAGS=-L$HOME/usr/lib
```

Assuming we are installing many package in `~/.usr`, and will always want to use these definitions of `CC`, `CPPFLAGS`, and `LDFLAGS`, we can automate this by creating the following `~/.usr/share/config.site` file:

```bash
test -z "$CC" && CC=gcc-3
test -z "$CPPFLAGS" && CPPFLAGS=-I$HOME/usr/include
test -z "$LDFLAGS" && LDFLAGS=-L$HOME/usr/lib
```

Now, any time a `configure` script is using the `~/.usr` prefix, it will execute the above `config.site` and define these three variables.

```
~/.amhello-1.0 % ./configure --prefix ~/.usr
configure: loading site script /home/adl/usr/share/config.site
```

... See Section “Setting Site Defaults” in *The Autoconf Manual*, for more information about this feature.

### 2.2.6 Parallel Build Trees (a.k.a. VPATH Builds)

The GNU Build System distinguishes two trees: the source tree, and the build tree.

The source tree is rooted in the directory containing `configure`. It contains all the sources files (those that are distributed), and may be arranged using several subdirectories.

The build tree is rooted in the directory in which `configure` was run, and is populated with all object files, programs, libraries, and other derived files built from the sources (and hence not distributed). The build tree usually has the same subdirectory layout as the source tree; its subdirectories are created automatically by the build system.

If `configure` is executed in its own directory, the source and build trees are combined: derived files are constructed in the same directories as their sources. This was the case in our first installation example (see Section 2.2.1 [Basic Installation], page 3).

A common request from users is that they want to confine all derived files to a single directory, to keep their source directories uncluttered. Here is how we could run `configure` to build everything in a subdirectory called `build/`.

These setups, where source and build trees are different, are often called *parallel builds* or *VPATH builds*. The expression *parallel build* is misleading: the word *parallel* is a reference to the way the build tree shadows the source tree, it is not about some concurrency in the way build commands are run. For this reason we refer to such setups using the name *VPATH builds* in the following. *VPATH* is the name of the *make* feature used by the *Makefiles* to allow these builds (see Section “VPATH Search Path for All Prerequisites” in *The GNU Make Manual*).

VPATH builds have other interesting uses. One is to build the same sources with multiple configurations. For instance:

```bash
~ % tar zxf ~/amhello-1.0.tar.gz
~ % cd amhello-1.0
~/amhello-1.0 % mkdir debug optim && cd debug
~/amhello-1.0/debug % ../configure CFLAGS='-g -O0'
... ~ /amhello-1.0/debug % make
... ~ /amhello-1.0/debug % cd ../optim
~/amhello-1.0/optim % ../configure CFLAGS='-O3 -fomit-frame-pointer'
... ~ /amhello-1.0/optim % make
...
```

With network file systems, a similar approach can be used to build the same sources on different machines. For instance, suppose that the sources are installed on a directory shared by two hosts: HOST1 and HOST2, which may be different platforms.

```bash
~ % tar zxf ~/amhello-1.0.tar.gz
~ % cd /nfs/src
/nfs/src % tar zxf ~/amhello-1.0.tar.gz
```

On the first host, you could create a local build directory:

```bash
[HOST1] ~ % mkdir /tmp/amh && cd /tmp/amh
[HOST1] /tmp/amh % /nfs/src/amhello-1.0/configure
...
[HOST1] /tmp/amh % make && sudo make install
... (Here we assume that the installer has configured *sudo* so it can execute *make install* with root privileges; it is more convenient than using *su* like in Section 2.2.1 [Basic Installation], page 3).
```

On the second host, you would do exactly the same, possibly at the same time:

```bash
[HOST2] ~ % mkdir /tmp/amh && cd /tmp/amh
[HOST2] /tmp/amh % /nfs/src/amhello-1.0/configure
```
2.2.7 Two-Part Installation

In our last example (see Section 2.2.6 [VPATH Builds], page 6), a source tree was shared by two hosts, but compilation and installation were done separately on each host.

The GNU Build System also supports networked setups where part of the installed files should be shared amongst multiple hosts. It does so by distinguishing architecture-dependent files from architecture-independent files, and providing two Makefile targets to install each of these classes of files.

These targets are `install-exec` for architecture-dependent files and `install-data` for architecture-independent files. The command we used up to now, `make install`, can be thought of as a shorthand for `make install-exec install-data`.

From the GNU Build System point of view, the distinction between architecture-dependent files and architecture-independent files is based exclusively on the directory variable used to specify their installation destination. In the list of directory variables we provided earlier (see Section 2.2.3 [Standard Directory Variables], page 4), all the variables based on `exec-prefix` designate architecture-dependent directories whose files will be installed by `make install-exec`. The others designate architecture-independent directories and will serve files installed by `make install-data`. See Section 12.2 [The Two Parts of Install], page 96, for more details.

Here is how we could revisit our two-host installation example, assuming that (1) we want to install the package directly in `/usr`, and (2) the directory `/usr/share` is shared by the two hosts.

On the first host we would run

```
[HOST1] ~ % mkdir /tmp/amh && cd /tmp/amh
[HOST1] /tmp/amh % /nfs/src/amhello-1.0/configure --prefix /usr
... [HOST1] /tmp/amh % make && sudo make install
...  
```

On the second host, however, we need only install the architecture-specific files.

```
[HOST2] ~ % mkdir /tmp/amh && cd /tmp/amh
[HOST2] /tmp/amh % /nfs/src/amhello-1.0/configure --prefix /usr
... [HOST2] /tmp/amh % make && sudo make install-exec
...  
```

In packages that have installation checks, it would make sense to run `make installcheck` (see Section 2.2.1 [Basic Installation], page 3) to verify that the package works correctly despite the apparent partial installation.
2.2.8 Cross-Compilation

To *cross-compile* is to build on one platform a binary that will run on another platform. When speaking of cross-compilation, it is important to distinguish between the *build platform* on which the compilation is performed, and the *host platform* on which the resulting executable is expected to run. The following `configure` options are used to specify each of them:

```
--build=build
   The system on which the package is built.

--host=host
   The system where built programs and libraries will run.
```

When the `--host` is used, `configure` will search for the cross-compiling suite for this platform. Cross-compilation tools commonly have their target architecture as prefix of their name. For instance my cross-compiler for MinGW32 has its binaries called `i586-mingw32msvc-gcc`, `i586-mingw32msvc-ld`, `i586-mingw32msvc-as`, etc.

Here is how we could build `amhello-1.0` for `i586-mingw32msvc` on a GNU/Linux PC.

```
~/amhello-1.0 % ./configure --build=i686-pc-linux-gnu --host=i586-mingw32msvc
```

```
checking for a BSD-compatible install... /usr/bin/install -c
checking whether build environment is sane... yes
cHECKING FOR GAWK... GAWK
checking whether make sets $(MAKE)... yes
cHECKING FOR I586-MINGW32MSVC-STRIP... i586-mingw32msvc-strip
checking for i586-mingw32msvc-gcc... i586-mingw32msvc-gcc
checking for C compiler default output file name... a.exe
checking whether the C compiler works... yes
cHECKING WHETHER WE ARE CROSS COMPILING... yes
cHECKING FOR SUFFIX OF EXECUTABLES... .exe
checking for suffix of object files... o
cHECKING WHETHER WE ARE USING THE GNU C COMPILER... yes
cHECKING WHETHER I586-MINGW32MSVC-GCC ACCEPTS -g... yes
checking for i586-mingw32msvc-gcc option to accept ANSI C... 
```

```
~/amhello-1.0 % make
```

```
~/amhello-1.0 % cd src; file hello.exe
hello.exe: MS Windows PE 32-bit Intel 80386 console executable not relocatable
```

The `--host` and `--build` options are usually all we need for cross-compiling. The only exception is if the package being built is itself a cross-compiler: we need a third option to specify its target architecture.

```
--target=target
   When building compiler tools: the system for which the tools will create output.
```

For instance when installing GCC, the GNU Compiler Collection, we can use `--target=target` to specify that we want to build GCC as a cross-compiler for `target`. Mixing `--build` and `--target`, we can actually cross-compile a cross-compiler; such a three-way cross-compilation is known as a *Canadian cross*.

See Section “Specifying the System Type” in *The Autoconf Manual*, for more information about these `configure` options.
2.2.9 Renaming Programs at Install Time

The GNU Build System provides means to automatically rename executables and manpages before they are installed (see Section 11.2 [Man Pages], page 94). This is especially convenient when installing a GNU package on a system that already has a proprietary implementation you do not want to overwrite. For instance, you may want to install GNU tar as gtar so you can distinguish it from your vendor’s tar.

This can be done using one of these three configure options.

--program-prefix=prefix
Prepend prefix to installed program names.

--program-suffix=suffix
Append suffix to installed program names.

--program-transform-name=program
Run sed program on installed program names.

The following commands would install hello as /usr/local/bin/test-hello, for instance.

```
~/amhello-1.0 % ./configure --program-prefix=test-
... 
~/amhello-1.0 % make
...
~/amhello-1.0 % sudo make install
...
```

2.2.10 Building Binary Packages Using DESTDIR

The GNU Build System’s make install and make uninstall interface does not exactly fit the needs of a system administrator who has to deploy and upgrade packages on lots of hosts. In other words, the GNU Build System does not replace a package manager.

Such package managers usually need to know which files have been installed by a package, so a mere make install is inappropriate.

The DESTDIR variable can be used to perform a staged installation. The package should be configured as if it was going to be installed in its final location (e.g., --prefix /usr), but when running make install, the DESTDIR should be set to the absolute name of a directory into which the installation will be diverted. From this directory it is easy to review which files are being installed where, and finally copy them to their final location by some means.

For instance here is how we could create a binary package containing a snapshot of all the files to be installed.

```
~/amhello-1.0 % ./configure --prefix /usr
...
~/amhello-1.0 % make
...
~/amhello-1.0 % make DESTDIR=$HOME/inst install
...
~/amhello-1.0 % cd ~/inst
~/inst % find . -type f -print > ../files.lst
```
"~/inst % tar zcvf ~/amhello-1.0-i686.tar.gz ‘cat ../files.lst’
./usr/bin/hello
./usr/share/doc/amhello/README

After this example, amhello-1.0-i686.tar.gz is ready to be uncompressed in / on
many hosts. (Using ‘cat ../files.lst’ instead of ‘.’ as argument for tar avoids entries
for each subdirectory in the archive: we would not like tar to restore the modification time
of /, /usr/, etc.)

Note that when building packages for several architectures, it might be convenient to use
make install-data and make install-exec (see Section 2.2.7 [Two-Part Install], page 8)
to gather architecture-independent files in a single package.

See Chapter 12 [Install], page 95, for more information.

2.2.11 Preparing Distributions

We have already mentioned make dist. This target collects all your source files and the
necessary parts of the build system to create a tarball named package-version.tar.gz.

Another, more useful command is make distcheck. The distcheck target constructs
package-version.tar.gz just as well as dist, but it additionally ensures most of the use
cases presented so far work:

- It attempts a full compilation of the package (see Section 2.2.1 [Basic Installation],
page 3), unpacking the newly constructed tarball, running make, make check, make
install, as well as make installcheck, and even make dist,
- it tests VPATH builds with read-only source tree (see Section 2.2.6 [VPATH Builds],
page 6),
- it makes sure make clean, make distclean, and make uninstall do not omit any file
(see Section 2.2.2 [Standard Targets], page 4),
- and it checks that DESTDIR installations work (see Section 2.2.10 [DESTDIR], page 10).

All of these actions are performed in a temporary subdirectory, so that no root privileges
are required.

Releasing a package that fails make distcheck means that one of the scenarios we pre-
sented will not work and some users will be disappointed. Therefore it is a good practice
to release a package only after a successful make distcheck. This of course does not imply
that the package will be flawless, but at least it will prevent some of the embarrassing errors
you may find in packages released by people who have never heard about distcheck (like
DESTDIR not working because of a typo, or a distributed file being erased by make clean,
or even VPATH builds not working).

See Section 2.4.1 [Creating amhello], page 13, to recreate amhello-1.0.tar.gz using
make distcheck. See Section 14.4 [Checking the Distribution], page 99, for more informa-
tion about distcheck.

2.2.12 Automatic Dependency Tracking

Dependency tracking is performed as a side-effect of compilation. Each time the build
system compiles a source file, it computes its list of dependencies (in C these are the header
files included by the source being compiled). Later, any time make is run and a dependency
appears to have changed, the dependent files will be rebuilt.
Automake generates code for automatic dependency tracking by default, unless the developer chooses to override it; for more information, see Section 8.19 [Dependencies], page 81.

When `configure` is executed, you can see it probing each compiler for the dependency mechanism it supports (several mechanisms can be used):

```
~/amhello-1.0 % ./configure --prefix /usr
...
  checking dependency style of gcc... gcc3
...
```

Because dependencies are only computed as a side-effect of the compilation, no dependency information exists the first time a package is built. This is OK because all the files need to be built anyway: `make` does not have to decide which files need to be rebuilt. In fact, dependency tracking is completely useless for one-time builds and there is a `configure` option to disable this:

```
--disable-dependency-tracking
  Speed up one-time builds.
```

Some compilers do not offer any practical way to derive the list of dependencies as a side-effect of the compilation, requiring a separate run (maybe of another tool) to compute these dependencies. The performance penalty implied by these methods is important enough to disable them by default. The option `--enable-dependency-tracking` must be passed to `configure` to activate them.

```
--enable-dependency-tracking
  Do not reject slow dependency extractors.
```

See Section 29.2 [Dependency Tracking Evolution], page 158, for some discussion about the different dependency tracking schemes used by Automake over the years.

### 2.2.13 Nested Packages

Although nesting packages isn’t something we would recommend to someone who is discovering the Autotools, it is a nice feature worthy of mention in this small advertising tour.

Autoconfiscated packages (that means packages whose build system have been created by Autoconf and friends) can be nested to arbitrary depth.

A typical setup is that package A will distribute one of the libraries it needs in a subdirectory. This library B is a complete package with its own GNU Build System. The `configure` script of A will run the `configure` script of B as part of its execution, building and installing A will also build and install B. Generating a distribution for A will also include B.

It is possible to gather several packages like this. GCC is a heavy user of this feature. This gives installers a single package to configure, build and install, while it allows developers to work on subpackages independently.

When configuring nested packages, the `configure` options given to the top-level `configure` are passed recursively to nested `configures`. A package that does not understand an option will ignore it, assuming it is meaningful to some other package.

The command `configure --help=recursive` can be used to display the options supported by all the included packages.
See Section 7.4 [Subpackages], page 52, for an example setup.

2.3 How Autotools Help

There are several reasons why you may not want to implement the GNU Build System yourself (read: write a configure script and Makefiles yourself).

- As we have seen, the GNU Build System has a lot of features (see Section 2.2 [Use Cases], page 2). Some users may expect features you have not implemented because you did not need them.

- Implementing these features portably is difficult and exhausting. Think of writing portable shell scripts, and portable Makefiles, for systems you may not have handy. See Section “Portable Shell Programming” in The Autoconf Manual, to convince yourself.

- You will have to upgrade your setup to follow changes to the GNU Coding Standards.

The GNU Autotools take all this burden off your back and provide:

- Tools to create a portable, complete, and self-contained GNU Build System, from simple instructions. Self-contained meaning the resulting build system does not require the GNU Autotools.

- A central place where fixes and improvements are made: a bug-fix for a portability issue will benefit every package.

Yet there also exist reasons why you may want NOT to use the Autotools... For instance you may be already using (or used to) another incompatible build system. Autotools will only be useful if you do accept the concepts of the GNU Build System. People who have their own idea of how a build system should work will feel frustrated by the Autotools.

2.4 A Small Hello World

In this section we recreate the amhello-1.0 package from scratch. The first subsection shows how to call the Autotools to instantiate the GNU Build System, while the second explains the meaning of the configure.ac and Makefile.am files read by the Autotools.

2.4.1 Creating amhello-1.0.tar.gz

Here is how we can recreate amhello-1.0.tar.gz from scratch. The package is simple enough so that we will only need to write 5 files. (You may copy them from the final amhello-1.0.tar.gz that is distributed with Automake if you do not want to write them.)

Create the following files in an empty directory.

- src/main.c is the source file for the hello program. We store it in the src/ subdirectory, because later, when the package evolves, it will ease the addition of a man/ directory for man pages, a data/ directory for data files, etc.

```bash
~/amhello % cat src/main.c
#include <config.h>
#include <stdio.h>

int
main (void)
```
Chapter 2: An Introduction to the Autotools

```c
{
    puts("Hello World!");
    puts("This is " PACKAGE_STRING ".");
    return 0;
}
```

- **README** contains some very limited documentation for our little package.
  ```
  ~/amhello % cat README
  This is a demonstration package for GNU Automake.
  Type ‘info Automake’ to read the Automake manual.
  ```

- **Makefile.am** and **src/Makefile.am** contain Automake instructions for these two directories.
  ```
  ~/amhello % cat src/Makefile.am
  bin_PROGRAMS = hello
  hello_SOURCES = main.c
  ~/amhello % cat Makefile.am
  SUBDIRS = src
  dist_doc_DATA = README
  ```

- Finally, **configure.ac** contains Autoconf instructions to create the **configure** script.
  ```
  ~/amhello % cat configure.ac
  AC_INIT([amhello], [1.0], [bug-automake@gnu.org])
  AM_INIT_AUTOMAKE([-Wall -Werror foreign])
  AC_PROG_CC
  AC_CONFIG_HEADERS([config.h])
  AC_CONFIG_FILES([
      Makefile
      src/Makefile
  ])
  AC_OUTPUT
  ```

Once you have these five files, it is time to run the Autotools to instantiate the build system. Do this using the **autoreconf** command as follows:
```
~/amhello % autoreconf --install
configure.ac: installing ‘./install-sh’
configure.ac: installing ‘./missing’
src/Makefile.am: installing ‘./depcomp’
```

At this point the build system is complete.

In addition to the three scripts mentioned in its output, you can see that **autoreconf** created four other files: **configure**, **config.h.in**, **Makefile.in**, and **src/Makefile.in**. The latter three files are templates that will be adapted to the system by **configure** under the names **config.h**, **Makefile**, and **src/Makefile**. Let’s do this:
```
~/amhello % ./configure
checking for a BSD-compatible install... /usr/bin/install -c
checking whether build environment is sane... yes
checking for gawk... no
checking for mawk... mawk
```
checking whether make sets $(MAKE)... yes
checking for gcc... gcc
checking for C compiler default output file name... a.out
checking whether the C compiler works... yes
checking whether we are cross compiling... no
checking for suffix of executables...
checking for suffix of object files... o
checking whether we are using the GNU C compiler... yes
checking whether gcc accepts -g... yes
checking for gcc option to accept ISO C89... none needed
checking for style of include used by make... GNU
checking dependency style of gcc... gcc3
configure: creating ./config.status
config.status: creating Makefile
config.status: creating src/Makefile
config.status: creating config.h
config.status: executing depfiles commands

You can see Makefile, src/Makefile, and config.h being created at the end after configure has probed the system. It is now possible to run all the targets we wish (see Section 2.2.2 [Standard Targets], page 4). For instance:

```
~/amhello % make
...
~/amhello % src/hello
Hello World!
~/amhello % make distcheck
...
============================================= amhello-1.0 archives ready for distribution:
  amhello-1.0.tar.gz
============================================= 
```

Note that running autoreconf is only needed initially when the GNU Build System does not exist. When you later change some instructions in a Makefile.am or configure.ac, the relevant part of the build system will be regenerated automatically when you execute make.

autoreconf is a script that calls autoconf, automake, and a bunch of other commands in the right order. If you are beginning with these tools, it is not important to figure out in which order all these tools should be invoked and why. However, because Autoconf and Automake have separate manuals, the important point to understand is that autoconf is in charge of creating configure from configure.ac, while automake is in charge of creating Makefile.ins from Makefile.ams and configure.ac. This should at least direct you to the right manual when seeking answers.

2.4.2 amhello’s configure.ac Setup Explained

Let us begin with the contents of configure.ac.

```
AC_INIT([amhello], [1.0], [bug-automake@gnu.org])
```
Chapter 2: An Introduction to the Autotools

AM_INIT_AUTOMAKE([-Wall -Werror foreign])
AC_PROG_CC
AC_CONFIG_HEADERS([config.h])
AC_CONFIG_FILES([Makefile
 src/Makefile
])
AC_OUTPUT

This file is read by both autoconf (to create configure) and automake (to create the various Makefile.in's). It contains a series of M4 macros that will be expanded as shell code to finally form the configure script. We will not elaborate on the syntax of this file, because the Autoconf manual has a whole section about it (see Section “Writing configure.ac” in The Autoconf Manual).

The macros prefixed with AC_ are Autoconf macros, documented in the Autoconf manual (see Section “Autoconf Macro Index” in The Autoconf Manual). The macros that start with AM_ are Automake macros, documented later in this manual (see Section B.1 [Macro Index], page 173).

The first two lines of configure.ac initialize Autoconf and Automake. AC_INIT takes in as parameters the name of the package, its version number, and a contact address for bug-reports about the package (this address is output at the end of ./configure --help, for instance). When adapting this setup to your own package, by all means please do not blindly copy Automake's address: use the mailing list of your package, or your own mail address.

The argument to AM_INIT_AUTOMAKE is a list of options for automake (see Chapter 17 [Options], page 107). -Wall and -Werror ask automake to turn on all warnings and report them as errors. We are speaking of Automake warnings here, such as dubious instructions in Makefile.am. This has absolutely nothing to do with how the compiler will be called, even though it may support options with similar names. Using -Wall -Werror is a safe setting when starting to work on a package: you do not want to miss any issues. Later you may decide to relax things a bit. The foreign option tells Automake that this package will not follow the GNU Standards. GNU packages should always distribute additional files such as ChangeLog, AUTHORS, etc. We do not want automake to complain about these missing files in our small example.

The AC_PROG_CC line causes the configure script to search for a C compiler and define the variable CC with its name. The src/Makefile.in file generated by Automake uses the variable CC to build hello, so when configure creates src/Makefile from src/Makefile.in, it will define CC with the value it has found. If Automake is asked to create a Makefile.in that uses CC but configure.ac does not define it, it will suggest you add a call to AC_PROG_CC.

The AC_CONFIG_HEADERS([config.h]) invocation causes the configure script to create a config.h file gathering #define's defined by other macros in configure.ac. In our case, the AC_INIT macro already defined a few of them. Here is an excerpt of config.h after configure has run:

.../* Define to the address where bug reports for this package should be sent. */
define PACKAGE_BUGREPORT "bug-automake@gnu.org"
/* Define to the full name and version of this package. */
define PACKAGE_STRING "amhello 1.0"

As you probably noticed, src/main.c includes config.h so it can use PACKAGE_STRING. In a real-world project, config.h can grow really big, with one ‘#define’ per feature probed on the system.

The AC_CONFIG_FILES macro declares the list of files that configure should create from their *.in templates. Automake also scans this list to find the Makefile.am files it must process. (This is important to remember: when adding a new directory to your project, you should add its Makefile to this list, otherwise Automake will never process the new Makefile.am you wrote in that directory.)

Finally, the AC_OUTPUT line is a closing command that actually produces the part of the script in charge of creating the files registered with AC_CONFIG_HEADERS and AC_CONFIG_FILES.

When starting a new project, we suggest you start with such a simple configure.ac, and gradually add the other tests it requires. The command autoscan can also suggest a few of the tests your package may need (see Section “Using autoscan to Create configure.ac” in The Autoconf Manual).

2.4.3 amhello’s Makefile.am Setup Explained

We now turn to src/Makefile.am. This file contains Automake instructions to build and install hello.

    bin_PROGRAMS = hello
    hello_SOURCES = main.c

A Makefile.am has the same syntax as an ordinary Makefile. When automake processes a Makefile.am it copies the entire file into the output Makefile.in (that will be later turned into Makefile by configure) but will react to certain variable definitions by generating some build rules and other variables. Often Makefile.am contains only a list of variable definitions as above, but they can also contain other variable and rule definitions that automake will pass along without interpretation.

Variables that end with _PROGRAMS are special variables that list programs that the resulting Makefile should build. In Automake speak, this _PROGRAMS suffix is called a primary; Automake recognizes other primaries such as _SCRIPTS, _DATA, _LIBRARIES, etc. corresponding to different types of files.

The ‘bin’ part of the bin_PROGRAMS tells automake that the resulting programs should be installed in bindir. Recall that the GNU Build System uses a set of variables to denote destination directories and allow users to customize these locations (see Section 2.2.3 [Standard Directory Variables], page 4). Any such directory variable can be put in front of a primary (omitting the dir suffix) to tell automake where to install the listed files.

Programs need to be built from source files, so for each program prog listed in a _PROGRAMS variable, automake will look for another variable named prog_SOURCES listing its source files. There may be more than one source file: they will all be compiled and linked together.
Automake also knows that source files need to be distributed when creating a tarball (unlike built programs). So a side-effect of this `hello_SOURCES` declaration is that `main.c` will be part of the tarball created by `make dist`.

Finally here are some explanations regarding the top-level `Makefile.am`.

```makefile
SUBDIRS = src
dist_doc_DATA = README
```

`SUBDIRS` is a special variable listing all directories that `make` should recurse into before processing the current directory. So this line is responsible for `make` building `src/hello` even though we run it from the top-level. This line also causes `make install` to install `src/hello` before installing `README` (not that this order matters).

The line `dist_doc_DATA = README` causes `README` to be distributed and installed in `docdir`. Files listed with the `_DATA` primary are not automatically part of the tarball built with `make dist`, so we add the `dist_` prefix so they get distributed. However, for `README` it would not have been necessary: `automake` automatically distributes any `README` file it encounters (the list of other files automatically distributed is presented by `automake --help`). The only important effect of this second line is therefore to install `README` during `make install`.

One thing not covered in this example is accessing the installation directory values (see Section 2.2.3 [Standard Directory Variables], page 4) from your program code, that is, converting them into defined macros. For this, see Section “Defining Directories” in [The Autoconf Manual](#).

# 3 General ideas

The following sections cover a few basic ideas that will help you understand how Automake works.

## 3.1 General Operation

Automake works by reading a `Makefile.am` and generating a `Makefile.in`. Certain variables and rules defined in the `Makefile.am` instruct Automake to generate more specialized code; for instance, a `bin_PROGRAMS` variable definition will cause rules for compiling and linking programs to be generated.

The variable definitions and rules in the `Makefile.am` are copied mostly verbatim into the generated file, with all variable definitions preceding all rules. This allows you to add almost arbitrary code into the generated `Makefile.in`. For instance, the Automake distribution includes a non-standard rule for the `git-dist` target, which the Automake maintainer uses to make distributions from the source control system.

Note that most GNU make extensions are not recognized by Automake. Using such extensions in a `Makefile.am` will lead to errors or confusing behavior.

A special exception is that the GNU make append operator, `+=`, is supported. This operator appends its right hand argument to the variable specified on the left. Automake will translate the operator into an ordinary `=` operator; `+=` will thus work with any make program.
Automake tries to keep comments grouped with any adjoining rules or variable definitions.

Generally, Automake is not particularly smart in the parsing of unusual Makefile constructs, so you’re advised to avoid fancy constructs or “creative” use of whitespaces. For example, TAB characters cannot be used between a target name and the following “:” character, and variable assignments shouldn’t be indented with TAB characters. Also, using more complex macro in target names can cause trouble:

```bash
% cat Makefile.am
$(FOO:=x): bar
% automake
Makefile.am:1: bad characters in variable name ‘$(FOO’
Makefile.am:1: ‘:’-style assignments are not portable
```

A rule defined in `Makefile.am` generally overrides any such rule of a similar name that would be automatically generated by `automake`. Although this is a supported feature, it is generally best to avoid making use of it, as sometimes the generated rules are very particular.

Similarly, a variable defined in `Makefile.am` or `AC_SUBST`ed from `configure.ac` will override any definition of the variable that `automake` would ordinarily create. This feature is more often useful than the ability to override a rule. Be warned that many of the variables generated by `automake` are considered to be for internal use only, and their names might change in future releases.

When examining a variable definition, Automake will recursively examine variables referenced in the definition. For example, if Automake is looking at the content of `foo_SOURCES` in this snippet

```bash
xs = a.c b.c
foo_SOURCES = c.c $(xs)
```

it would use the files `a.c`, `b.c`, and `c.c` as the contents of `foo_SOURCES`.

Automake also allows a form of comment that is not copied into the output; all lines beginning with `##` (leading spaces allowed) are completely ignored by Automake.

It is customary to make the first line of `Makefile.am` read:

```
## Process this file with automake to produce Makefile.in
```

### 3.2 Strictness

While Automake is intended to be used by maintainers of GNU packages, it does make some effort to accommodate those who wish to use it, but do not want to use all the GNU conventions.

To this end, Automake supports three levels of strictness—the strictness indicating how stringently Automake should check standards conformance.

The valid strictness levels are:

- **foreign**: Automake will check for only those things that are absolutely required for proper operations. For instance, whereas GNU standards dictate the existence of a `NEWS` file, it will not be required in this mode. The name comes from the fact that Automake is intended to be used for GNU programs; these relaxed rules are not the standard mode of operation.
Automake will check—as much as possible—for compliance to the GNU standards for packages. This is the default.

Automake will check for compliance to the as-yet-unwritten Gnits standards. These are based on the GNU standards, but are even more detailed. Unless you are a Gnits standards contributor, it is recommended that you avoid this option until such time as the Gnits standard is actually published (which may never happen).

See Chapter 22 [Gnits], page 120, for more information on the precise implications of the strictness level.

Automake also has a special (and today deprecated) “cygnus” mode that is similar to strictness but handled differently. This mode is useful for packages that are put into a “Cygnus” style tree (e.g., older versions of the GCC and gdb trees). See Chapter 23 [Cygnus], page 121, for more information on this mode. Please note that this mode is deprecated and will be removed in the future automake versions; you must avoid its use in new packages, and should stop using it in existing packages as well.

### 3.3 The Uniform Naming Scheme

Automake variables generally follow a uniform naming scheme that makes it easy to decide how programs (and other derived objects) are built, and how they are installed. This scheme also supports configure time determination of what should be built.

At make time, certain variables are used to determine which objects are to be built. The variable names are made of several pieces that are concatenated together.

The piece that tells automake what is being built is commonly called the primary. For instance, the primary PROGRAMS holds a list of programs that are to be compiled and linked.

A different set of names is used to decide where the built objects should be installed. These names are prefixes to the primary, and they indicate which standard directory should be used as the installation directory. The standard directory names are given in the GNU standards (see Section “Directory Variables” in The GNU Coding Standards). Automake extends this list with pkgdatadir, pkgincludedir, pkglibdir, and pkglibexecdir; these are the same as the non-’pkg’ versions, but with ‘$(PACKAGE)’ appended. For instance, pkglibdir is defined as ‘$(libdir)/$(PACKAGE)’.

For each primary, there is one additional variable named by prepending ‘EXTRA_’ to the primary name. This variable is used to list objects that may or may not be built, depending on what configure decides. This variable is required because Automake must statically know the entire list of objects that may be built in order to generate a Makefile.in that will work in all cases.

For instance, cpio decides at configure time which programs should be built. Some of the programs are installed in bindir, and some are installed in sbindir:

```bash
EXTRA_PROGRAMS = mt rmt
bin_PROGRAMS = cpio pax
sbin_PROGRAMS = $(MORE_PROGRAMS)
```

Defining a primary without a prefix as a variable, e.g., ‘PROGRAMS’, is an error.
Note that the common ‘dir’ suffix is left off when constructing the variable names; thus one writes ‘bin_PROGRAMS’ and not ‘bindir_PROGRAMS’.

Not every sort of object can be installed in every directory. Automake will flag those attempts if finds in error (but see below how to override the check if you really need to). Automake will also diagnose obvious misspellings in directory names.

Sometimes the standard directories—even as augmented by Automake—are not enough. In particular it is sometimes useful, for clarity, to install objects in a subdirectory of some predefined directory. To this end, Automake allows you to extend the list of possible installation directories. A given prefix (e.g., ‘zar’) is valid if a variable of the same name with ‘dir’ appended is defined (e.g., ‘zardir’).

For instance, the following snippet will install file.xml into ‘$(datadir)/xml’.

```plaintext
xmldir = $(datadir)/xml
xml_DATA = file.xml
```

This feature can also be used to override the sanity checks Automake performs to diagnose suspicious directory/primary couples (in the unlikely case these checks are undesirable, and you really know what you’re doing). For example, Automake would error out on this input:

```plaintext
# Forbidden directory combinations, automake will error out on this.
pkglib_PROGRAMS = foo
doc_LIBRARIES = libquux.a
```

but it will succeed with this:

```plaintext
# Work around forbidden directory combinations. Do not use this
# without a very good reason!
my_execbindir = $(pkglibdir)
my_doclibdir = $(docdir)
my_execbin_PROGRAMS = foo
my_doclib_LIBRARIES = libquux.a
```

The ‘exec’ substring of the ‘my_execbindir’ variable lets the files be installed at the right time (see Section 12.2 [The Two Parts of Install], page 96).

The special prefix ‘noinst_’ indicates that the objects in question should be built but not installed at all. This is usually used for objects required to build the rest of your package, for instance static libraries (see Section 8.2 [A Library], page 58), or helper scripts.

The special prefix ‘check_’ indicates that the objects in question should not be built until the ‘make check’ command is run. Those objects are not installed either.

Some primaries also allow additional prefixes that control other aspects of automake’s behavior. The currently defined prefixes are ‘dist_’, ‘nodist_’, ‘nобase_’, and ‘notrans_’. These prefixes are explained later (see Section 8.4 [Program and Library Variables], page 65) (see Section 11.2 [Man Pages], page 94).
3.4 Staying below the command line length limit

Traditionally, most unix-like systems have a length limitation for the command line arguments and environment contents when creating new processes (see for example http://www.in-ulm.de/~mascheck/various/argmax/ for an overview on this issue), which of course also applies to commands spawned by make. POSIX requires this limit to be at least 4096 bytes, and most modern systems have quite high limits (or are unlimited).

In order to create portable Makefiles that do not trip over these limits, it is necessary to keep the length of file lists bounded. Unfortunately, it is not possible to do so fully transparently within Automake, so your help may be needed. Typically, you can split long file lists manually and use different installation directory names for each list. For example,

\[
\text{data\_DATA} = \text{file1} \ldots \text{fileN} \text{ fileN+1} \ldots \text{file2N}
\]

may also be written as

\[
\text{data\_DATA} = \text{file1} \ldots \text{fileN} \\
\text{data2dir} = \$(\text{datadir}) \\
\text{data2\_DATA} = \text{fileN+1} \ldots \text{file2N}
\]

and will cause Automake to treat the two lists separately during make install. See Section 12.2 [The Two Parts of Install], page 96, for choosing directory names that will keep the ordering of the two parts of installation. Note that make dist may still only work on a host with a higher length limit in this example.

Automake itself employs a couple of strategies to avoid long command lines. For example, when ‘${\text{srcdir}}’/ is prepended to file names, as can happen with above \$(\text{data\_DATA}) lists, it limits the amount of arguments passed to external commands.

Unfortunately, some system’s make commands may prepend VPATH prefixes like ‘${\text{srcdir}}’/ to file names from the source tree automatically (see Section “Automatic Rule Rewriting” in The Autoconf Manual). In this case, the user may have to switch to use GNU Make, or refrain from using VPATH builds, in order to stay below the length limit.

For libraries and programs built from many sources, convenience archives may be used as intermediates in order to limit the object list length (see Section 8.3.5 [Libtool Convenience Libraries], page 61).

3.5 How derived variables are named

Sometimes a Makefile variable name is derived from some text the maintainer supplies. For instance, a program name listed in ‘_PROGRAMS’ is rewritten into the name of a ‘_SOURCES’ variable. In cases like this, Automake canonicalizes the text, so that program names and the like do not have to follow Makefile variable naming rules. All characters in the name except for letters, numbers, the strudel (@), and the underscore are turned into underscores when making variable references.

For example, if your program is named sniff-glue, the derived variable name would be ‘sniff\_glue\_SOURCES’, not ‘sniff-glue\_SOURCES’. Similarly the sources for a library named libmumble++.a should be listed in the ‘libmumble___a\_SOURCES’ variable.

The strudel is an addition, to make the use of Autoconf substitutions in variable names less obfuscating.
3.6 Variables reserved for the user

Some Makefile variables are reserved by the GNU Coding Standards for the use of the “user”—the person building the package. For instance, \texttt{CFLAGS} is one such variable.

Sometimes package developers are tempted to set user variables such as \texttt{CFLAGS} because it appears to make their job easier. However, the package itself should never set a user variable, particularly not to include switches that are required for proper compilation of the package. Since these variables are documented as being for the package builder, that person rightfully expects to be able to override any of these variables at build time.

To get around this problem, Automake introduces an automake-specific shadow variable for each user flag variable. (Shadow variables are not introduced for variables like \texttt{CC}, where they would make no sense.) The shadow variable is named by prepending ‘\texttt{AM}_’ to the user variable’s name. For instance, the shadow variable for \texttt{YFLAGS} is \texttt{AM\_YFLAGS}. The package maintainer—that is, the author(s) of the Makefile.am and configure.ac files—may adjust these shadow variables however necessary.

See Section 28.6 [Flag Variables Ordering], page 134, for more discussion about these variables and how they interact with per-target variables.

3.7 Programs automake might require

Automake sometimes requires helper programs so that the generated Makefile can do its work properly. There are a fairly large number of them, and we list them here.

Although all of these files are distributed and installed with Automake, a couple of them are maintained separately. The Automake copies are updated before each release, but we mention the original source in case you need more recent versions.

\texttt{ar-lib} \hspace{1cm} This is a wrapper primarily for the Microsoft lib archiver, to make it more POSIX-like.

\texttt{ans12knr.c} \hspace{1cm} \texttt{ans12knr.1}

These two files are used for de-ANSI-fication support (they are deprecated now, and \textit{will be removed} in the next major Automake release; see Section 8.18 [ANSI], page 80).

\texttt{compile} \hspace{1cm} This is a wrapper for compilers that do not accept options \texttt{-c} and \texttt{-o} at the same time. It is only used when absolutely required. Such compilers are rare, with the Microsoft C/C++ Compiler as the most notable exception. This wrapper also makes the following common options available for that compiler, while performing file name translation where needed: \texttt{-I}, \texttt{-L}, \texttt{-l}, \texttt{-Wl}, and \texttt{-Xlinker}.

\texttt{config.guess} \hspace{1cm} \texttt{config.sub}

These two programs compute the canonical triplets for the given build, host, or target architecture. These programs are updated regularly to support new architectures and fix probes broken by changes in new kernel versions. Each new release of Automake comes with up-to-date copies of these programs. If your copy of Automake is getting old, you are encouraged to fetch the latest versions of these files from \url{http://savannah.gnu.org/git/?group=config} before making a release.
config-ml.in
This file is not a program, it is a configure fragment used for multilib support (see Section 18.3 [Multilibs], page 113). Since the Automake multilib support has been deprecated and targeted for removal, this file is going to be removed from the Automake core in the next major release. The master copy of this file is maintained in the GCC tree at http://gcc.gnu.org/svn.html.

decom
This program understands how to run a compiler so that it will generate not only the desired output but also dependency information that is then used by the automatic dependency tracking feature (see Section 8.19 [Dependencies], page 81).
elisp-comp
This program is used to byte-compile Emacs Lisp code.
install-sh
This is a replacement for the install program that works on platforms where install is unavailable or unusable.
mdate-sh
This script is used to generate a version.texi file. It examines a file and prints some date information about it.
missing
This wraps a number of programs that are typically only required by maintainers. If the program in question doesn’t exist, missing prints an informative warning and attempts to fix things so that the build can continue.
mkinstalldirs
This script used to be a wrapper around ‘mkdir -p’, which is not portable. Now we prefer to use ‘install-sh -d’ when configure finds that ‘mkdir -p’ does not work, this makes one less script to distribute.
For backward compatibility mkinstalldirs is still used and distributed when automake finds it in a package. But it is no longer installed automatically, and it should be safe to remove it.
py-compile
This is used to byte-compile Python scripts.
symlink-tree
This program duplicates a tree of directories, using symbolic links instead of copying files. Such an operation is performed when building multilibs (see Section 18.3 [Multilibs], page 113). Since the Automake multilib support has been deprecated and targeted for removal, this file is going to be removed from the Automake core in the next major release. The master copy of this file is maintained in the GCC tree at http://gcc.gnu.org/svn.html.
texinfo.tex
Not a program, this file is required for ‘make dvi’, ‘make ps’ and ‘make pdf’ to work when Texinfo sources are in the package. The latest version can be downloaded from http://www.gnu.org/software/texinfo/.
ylwrap
This program wraps lex and yacc to rename their output files. It also ensures that, for instance, multiple yacc instances can be invoked in a single directory in parallel.
4 Some example packages

This section contains two small examples.

The first example (see Section 4.1 [Complete], page 25) assumes you have an existing project already using Autoconf, with handcrafted Makefiles, and that you want to convert it to using Automake. If you are discovering both tools, it is probably better that you look at the Hello World example presented earlier (see Section 2.4 [Hello World], page 13).

The second example (see Section 4.2 [true], page 26) shows how two programs can be built from the same file, using different compilation parameters. It contains some technical digressions that are probably best skipped on first read.

4.1 A simple example, start to finish

Let’s suppose you just finished writing zardoz, a program to make your head float from vortex to vortex. You’ve been using Autoconf to provide a portability framework, but your Makefile.in files have been ad-hoc. You want to make them bulletproof, so you turn to Automake.

The first step is to update your configure.ac to include the commands that automake needs. The way to do this is to add an AM_INIT_AUTOMAKE call just after AC_INIT:

```
AC_INIT([zardoz], [1.0])
AM_INIT_AUTOMAKE
...
```

Since your program doesn’t have any complicating factors (e.g., it doesn’t use gettext, it doesn’t want to build a shared library), you’re done with this part. That was easy!

Now you must regenerate configure. But to do that, you’ll need to tell autoconf how to find the new macro you’ve used. The easiest way to do this is to use the aclocal program to generate your aclocal.m4 for you. But wait... maybe you already have an aclocal.m4, because you had to write some hairy macros for your program. The aclocal program lets you put your own macros into acinclude.m4, so simply rename and then run:

```
mv aclocal.m4 acinclude.m4
aclocal
autoconf
```

Now it is time to write your Makefile.am for zardoz. Since zardoz is a user program, you want to install it where the rest of the user programs go: bindir. Additionally, zardoz has some TeXinfo documentation. Your configure.ac script uses AC_REPLACE_FUNCS, so you need to link against `$LIBOBJS' . So here’s what you’d write:

```
bin_PROGRAMS = zardoz
zardoz_SOURCES = main.c head.c float.c vortex9.c gun.c
zardoz_LDADD = $(LIBOBJS)

info_TEXINFOS = zardoz.texi
```

Now you can run ‘automake --add-missing’ to generate your Makefile.in and grab any auxiliary files you might need, and you’re done!
4.2 Building true and false

Here is another, trickier example. It shows how to generate two programs (true and false) from the same source file (true.c). The difficult part is that each compilation of true.c requires different cpp flags.

```plaintext
bin_PROGRAMS = true false
false_SOURCES =
false_LDADD = false.o

true.o: true.c
   $(COMPILE) -DEXIT_CODE=0 -c true.c

false.o: true.c
   $(COMPILE) -DEXIT_CODE=1 -o false.o -c true.c
```

Note that there is no true_SOURCES definition. Automake will implicitly assume that there is a source file named true.c (see Section 8.5 [Default SOURCES], page 69), and define rules to compile true.o and link true. The 'true.o: true.c' rule supplied by the above Makefile.am, will override the Automake generated rule to build true.o.

false_SOURCES is defined to be empty—that way no implicit value is substituted. Because we have not listed the source of false, we have to tell Automake how to link the program. This is the purpose of the false_LDADD line. A false_DEPENDENCIES variable, holding the dependencies of the false target will be automatically generated by Automake from the content of false_LDADD.

The above rules won’t work if your compiler doesn’t accept both -c and -o. The simplest fix for this is to introduce a bogus dependency (to avoid problems with a parallel make):

```plaintext
true.o: true.c false.o
   $(COMPILE) -DEXIT_CODE=0 -c true.c

false.o: true.c
   $(COMPILE) -DEXIT_CODE=1 -c true.c && mv true.o false.o
```

As it turns out, there is also a much easier way to do this same task. Some of the above technique is useful enough that we’ve kept the example in the manual. However if you were to build true and false in real life, you would probably use per-program compilation flags, like so:

```plaintext
bin_PROGRAMS = false true
false_SOURCES = true.c
false_CPPFLAGS = -DEXIT_CODE=1

true_SOURCES = true.c
true_CPPFLAGS = -DEXIT_CODE=0
```

In this case Automake will cause true.c to be compiled twice, with different flags. In this instance, the names of the object files would be chosen by automake; they would be false-true.o and true-true.o. (The name of the object files rarely matters.)
Chapter 5: Creating a Makefile.in

5 Creating a Makefile.in

To create all the `Makefile.in` files for a package, run the `automake` program in the top level directory, with no arguments. `automake` will automatically find each appropriate `Makefile.am` (by scanning `configure.ac`; see Chapter 6 [configure], page 30) and generate the corresponding `Makefile.in`. Note that `automake` has a rather simplistic view of what constitutes a package; it assumes that a package has only one `configure.ac`, at the top. If your package has multiple `configure.ac` files, then you must run `automake` in each directory holding a `configure.ac`. (Alternatively, you may rely on Autoconf's `autoreconf`, which is able to recurse your package tree and run `automake` where appropriate.)

You can optionally give `automake` an argument; `.am` is appended to the argument and the result is used as the name of the input file. This feature is generally only used to automatically rebuild an out-of-date `Makefile.in`. Note that `automake` must always be run from the topmost directory of a project, even if being used to regenerate the `Makefile.in` in some subdirectory. This is necessary because `automake` must scan `configure.ac`, and because `automake` uses the knowledge that a `Makefile.in` is in a subdirectory to change its behavior in some cases.

Automake will run `autoconf` to scan `configure.ac` and its dependencies (i.e., `aclocal.m4` and any included file), therefore `autoconf` must be in your `PATH`. If there is an `AUTOCONF` variable in your environment it will be used instead of `autoconf`, this allows you to select a particular version of Autoconf. By the way, don't misunderstand this paragraph: `automake` runs `autoconf` to scan your `configure.ac`, this won't build `configure` and you still have to run `autoconf` yourself for this purpose.

`automake` accepts the following options:

-a
--add-missing

Automake requires certain common files to exist in certain situations; for instance, `config.guess` is required if `configure.ac` invokes `AC_CANONICAL_HOST`. Automake is distributed with several of these files (see Section 3.7 [Auxiliary Programs], page 23); this option will cause the missing ones to be automatically added to the package, whenever possible. In general if Automake tells you a file is missing, try using this option. By default Automake tries to make a symbolic link pointing to its own copy of the missing file; this can be changed with `--copy`.

Many of the potentially-missing files are common scripts whose location may be specified via the `AC_CONFIG_AUX_DIR` macro. Therefore, `AC_CONFIG_AUX_DIR`'s setting affects whether a file is considered missing, and where the missing file is added (see Section 6.2 [Optional], page 32).

In some strictness modes, additional files are installed, see Chapter 22 [Gnits], page 120, for more information.

--libdir=dir

Look for Automake data files in directory `dir` instead of in the installation directory. This is typically used for debugging.
-c
--copy When used with --add-missing, causes installed files to be copied. The default is to make a symbolic link.

--cygnus Causes the generated Makefile.in files to follow Cygnus rules, instead of GNU or Gnits rules. For more information, see Chapter 23 [Cygnus], page 121. Note that this mode of operation is deprecated, and will be removed in a future Automake release.

-f
--force-missing When used with --add-missing, causes standard files to be reinstalled even if they already exist in the source tree. This involves removing the file from the source tree before creating the new symlink (or, with --copy, copying the new file).

--foreign Set the global strictness to foreign. For more information, see Section 3.2 [Strictness], page 19.

--gnits Set the global strictness to gnits. For more information, see Chapter 22 [Gnits], page 120.

--gnu Set the global strictness to gnu. For more information, see Chapter 22 [Gnits], page 120. This is the default strictness.

--help Print a summary of the command line options and exit.

-i
--ignore-deps This disables the dependency tracking feature in generated Makefiles; see Section 8.19 [Dependencies], page 81.

--include-deps This enables the dependency tracking feature. This feature is enabled by default. This option is provided for historical reasons only and probably should not be used.

--no-force Ordinarily automake creates all Makefile.ins mentioned in configure.ac. This option causes it to only update those Makefile.ins that are out of date with respect to one of their dependents.

-o dir
--output-dir=dir Put the generated Makefile.in in the directory dir. Ordinarily each Makefile.in is created in the directory of the corresponding Makefile.am. This option is deprecated and will be removed in a future release.

-v
--verbose Cause Automake to print information about which files are being read or created.
--version
Print the version number of Automake and exit.

-W CATEGORY
--warnings=category
Output warnings falling in category. category can be one of:

gnu          warnings related to the GNU Coding Standards (see The GNU Coding Standards).
obsolete     obsolete features or constructions
override     user redefinitions of Automake rules or variables
portability  portability issues (e.g., use of make features that are known to be not portable)
extra-portability extra portability issues related to obscure tools. One example of such a tool is the Microsoft lib archiver.
syntax       weird syntax, unused variables, typos
unsupported   unsupported or incomplete features
all           all the warnings
none          turn off all the warnings
error         treat warnings as errors

A category can be turned off by prefixing its name with ‘no-‘. For instance, -Wno-syntax will hide the warnings about unused variables.
The categories output by default are ‘syntax’ and ‘unsupported’. Additionally, ‘gnu’ and ‘portability’ are enabled in --gnu and --gnits strictness. On the other hand, the silent-rules options (see Chapter 17 [Options], page 107) turns off portability warnings about recursive variable expansions.
Turning off ‘portability’ will also turn off ‘extra-portability’, and similarly turning on ‘extra-portability’ will also turn on ‘portability’. However, turning on ‘portability’ or turning off ‘extra-portability’ will not affect the other category.
The environment variable WARNINGS can contain a comma separated list of categories to enable. It will be taken into account before the command-line switches, this way -Wnone will also ignore any warning category enabled by WARNINGS. This variable is also used by other tools like autoconf; unknown categories are ignored for this reason.

If the environment variable AUTOMAKE_JOBS contains a positive number, it is taken as the maximum number of Perl threads to use in automake for generating multiple Makefile.in files concurrently. This is an experimental feature.
Chapter 6: Scanning configure.ac, using aclocal

6 Scanning configure.ac, using aclocal

Automake scans the package's configure.ac to determine certain information about the package. Some autoconf macros are required and some variables must be defined in configure.ac. Automake will also use information from configure.ac to further tailor its output.

Automake also supplies some Autoconf macros to make the maintenance easier. These macros can automatically be put into your aclocal.m4 using the aclocal program.

6.1 Configuration requirements

The one real requirement of Automake is that your configure.ac call AM_INIT_AUTOMAKE. This macro does several things that are required for proper Automake operation (see Section 6.4 [Macros], page 44).

Here are the other macros that Automake requires but which are not run by AM_INIT_AUTOMAKE:

AC_CONFIG_FILES
AC_OUTPUT

These two macros are usually invoked as follows near the end of configure.ac.

...  
AC_CONFIG_FILES([  
  Makefile  
doc/Makefile  
src/Makefile  
src/lib/Makefile  
...  
])  
AC_OUTPUT

Automake uses these to determine which files to create (see Section “Creating Output Files” in The Autoconf Manual). A listed file is considered to be an Automake generated Makefile if there exists a file with the same name and the .am extension appended. Typically, ‘AC_CONFIG_FILES([foo/Makefile])’ will cause Automake to generate foo/Makefile.in if foo/Makefile.am exists.

When using AC_CONFIG_FILES with multiple input files, as in

AC_CONFIG_FILES([Makefile:top.in:Makefile.in:bot.in])

automake will generate the first .in input file for which a .am file exists. If no such file exists the output file is not considered to be generated by Automake.

Files created by AC_CONFIG_FILES, be they Automake Makefiles or not, are all removed by ‘make distclean’. Their inputs are automatically distributed, unless they are the output of prior AC_CONFIG_FILES commands. Finally, rebuild rules are generated in the Automake Makefile existing in the subdirectory of the output file, if there is one, or in the top-level Makefile otherwise.

The above machinery (cleaning, distributing, and rebuilding) works fine if the AC_CONFIG_FILES specifications contain only literals. If part of the specification
uses shell variables, `automake` will not be able to fulfill this setup, and you will have to complete the missing bits by hand. For instance, on

```bash
file=input
...
AC_CONFIG_FILES([output:$file], [file=$file])
```

`automake` will output rules to clean `output`, and rebuild it. However the rebuild rule will not depend on `input`, and this file will not be distributed either. (You must add `EXTRA_DIST = input` to your `Makefile.am` if `input` is a source file.)

Similarly

```bash
file=output
file2=out:in
...
AC_CONFIG_FILES([$file:input], [file=$file])
AC_CONFIG_FILES([$file2], [file2=$file2])
```

will only cause `input` to be distributed. No file will be cleaned automatically (add `DISTCLEANFILES = output out` yourself), and no rebuild rule will be output.

Obviously `automake` cannot guess what value `$file` is going to hold later when `configure` is run, and it cannot use the shell variable `$file` in a `Makefile`. However, if you make reference to `$file` as `${file}` (i.e., in a way that is compatible with `make`'s syntax) and furthermore use `AC_SUBST` to ensure that `${file}` is meaningful in a `Makefile`, then `automake` will be able to use `${file}` to generate all these rules. For instance, here is how the Automake package itself generates versioned scripts for its test suite:

```bash
AC_SUBST([APIVERSION], ...)
...
AC_CONFIG_FILES(
    [tests/aclocal-${APIVERSION}:tests/aclocal.in],
    [chmod +x tests/aclocal-${APIVERSION}],
    [APIVERSION=${APIVERSION}])
AC_CONFIG_FILES(
    [tests/automake-${APIVERSION}:tests/automake.in],
    [chmod +x tests/automake-${APIVERSION}])
```

Here cleaning, distributing, and rebuilding are done automatically, because `${APIVERSION}` is known at `make`-time.

Note that you should not use shell variables to declare `Makefile` files for which `automake` must create `Makefile.in`. Even `AC_SUBST` does not help here, because `automake` needs to know the file name when it runs in order to check whether `Makefile.am` exists. (In the very hairy case that your setup requires such use of variables, you will have to tell Automake which `Makefile.ins` to generate on the command-line.)

It is possible to let `automake` emit conditional rules for `AC_CONFIG_FILES` with the help of `AM_COND_IF` (see Section 6.2 [Optional], page 32).

To summarize:

- Use literals for `Makefiles`, and for other files whenever possible.
• Use ‘$file’ (or ‘${file}’) without ‘AC_SUBST([file])’) for files that automake should ignore.
• Use '${file}' and ‘AC_SUBST([file])’ for files that automake should not ignore.

6.2 Other things Automake recognizes

Every time Automake is run it calls Autoconf to trace configure.ac. This way it can recognize the use of certain macros and tailor the generated Makefile.in appropriately. Currently recognized macros and their effects are:

AC_CANONICAL_BUILD
AC_CANONICAL_HOST
AC_CANONICAL_TARGET
Automake will ensure that config.guess and config.sub exist. Also, the Makefile variables build_triplet, host_triplet and target_triplet are introduced. See Section “Getting the Canonical System Type” in The Autoconf Manual.

AC_CONFIG_AUX_DIR
Automake will look for various helper scripts, such as install-sh, in the directory named in this macro invocation. (The full list of scripts is: ar-lib, config.guess, config.sub, depcomp, elisp-comp, compile, install-sh, ltmain.sh, mdate-sh, missing, mkinstalldirs, py-compile, texinfo.tex, and ylwrap.) Not all scripts are always searched for; some scripts will only be sought if the generated Makefile.in requires them.
If AC_CONFIG_AUX_DIR is not given, the scripts are looked for in their standard locations. For mdate-sh, texinfo.tex, and ylwrap, the standard location is the source directory corresponding to the current Makefile.am. For the rest, the standard location is the first one of .., ..., or ../.. (relative to the top source directory) that provides any one of the helper scripts. See Section “Finding ‘configure’ Input” in The Autoconf Manual.
Required files from AC_CONFIG_AUX_DIR are automatically distributed, even if there is no Makefile.am in this directory.

AC_CONFIG_LIBOBJ_DIR
Automake will require the sources file declared with AC_LIBSOURCE (see below) in the directory specified by this macro.

AC_CONFIG_HEADERS
Automake will generate rules to rebuild these headers. Older versions of Automake required the use of AM_CONFIG_HEADER (see Section 6.4 [Macros], page 44); this is no longer the case.
As with AC_CONFIG_FILES (see Section 6.1 [Requirements], page 30), parts of the specification using shell variables will be ignored as far as cleaning, distributing, and rebuilding is concerned.

AC_CONFIG_LINKS
Automake will generate rules to remove configure generated links on ‘make distclean’ and to distribute named source files as part of ‘make dist’.
As for AC_CONFIG_FILES (see Section 6.1 [Requirements], page 30), parts of the specification using shell variables will be ignored as far as cleaning and distributing is concerned. (There are no rebuild rules for links.)

**AC_LIBOBJ**
**AC_LIBSOURCE**
**AC_LIBSOURCES**

Automake will automatically distribute any file listed in AC_LIBSOURCE or AC_LIBSOURCES.

Note that the AC_LIBOBJ macro calls AC_LIBSOURCE. So if an Autoconf macro is documented to call `AC_LIBOBJ([file])`, then file.c will be distributed automatically by Automake. This encompasses many macros like AC_FUNC_ALLOCA, AC_FUNC_MEMCMP, AC_REPLACE_FUNCS, and others.

By the way, direct assignments to LIBOBJS are no longer supported. You should always use AC_LIBOBJ for this purpose. See Section “AC_LIBOBJ vs. LIBOBJS” in *The Autoconf Manual*.

**AC_PROG_RANLIB**

This is required if any libraries are built in the package. See Section “Particular Program Checks” in *The Autoconf Manual*.

**AC_PROG_CXX**

This is required if any C++ source is included. See Section “Particular Program Checks” in *The Autoconf Manual*.

**AC_PROG_OBJC**

This is required if any Objective C source is included. See Section “Particular Program Checks” in *The Autoconf Manual*.

**AC_PROG_F77**

This is required if any Fortran 77 source is included. This macro is distributed with Autoconf version 2.13 and later. See Section “Particular Program Checks” in *The Autoconf Manual*.

**AC_F77_LIBRARY_LDFLAGS**

This is required for programs and shared libraries that are a mixture of languages that include Fortran 77 (see Section 8.13.3 [Mixing Fortran 77 With C and C++], page 77). See Section 6.4 [Autoconf macros supplied with Automake], page 44.

**AC_FC_SRCEXT**

Automake will add the flags computed by AC_FC_SRCEXT to compilation of files with the respective source extension (see Section “Fortran Compiler Characteristics” in *The Autoconf Manual*).

**AC_PROG_FC**

This is required if any Fortran 90/95 source is included. This macro is distributed with Autoconf version 2.58 and later. See Section “Particular Program Checks” in *The Autoconf Manual*. 
Chapter 6: Scanning configure.ac, using aclocal

AC_PROG_LIBTOOL
Automake will turn on processing for libtool (see Section “Introduction” in The Libtool Manual).

AC_PROG_YACC
If a Yacc source file is seen, then you must either use this macro or define the variable YACC in configure.ac. The former is preferred (see Section “Particular Program Checks” in The Autoconf Manual).

AC_PROG_LEX
If a Lex source file is seen, then this macro must be used. See Section “Particular Program Checks” in The Autoconf Manual.

AC_REQUIRE_AUX_FILE
For each AC_REQUIRE_AUX_FILE([file]), automake will ensure that file exists in the aux directory, and will complain otherwise. It will also automatically distribute the file. This macro should be used by third-party Autoconf macros that require some supporting files in the aux directory specified with AC_CONFIG_AUX_DIR above. See Section “Finding configure Input” in The Autoconf Manual.

AC_SUBST
The first argument is automatically defined as a variable in each generated Makefile.in, unless AM_SUBST_NOTMAKE is also used for this variable. See Section “Setting Output Variables” in The Autoconf Manual.

For every substituted variable var, automake will add a line var = value to each Makefile.in file. Many Autoconf macros invoke AC_SUBST to set output variables this way, e.g., AC_PATH_XTRA defines X_CFLAGS and X_LIBS. Thus, you can access these variables as $(X_CFLAGS) and $(X_LIBS) in any Makefile.am if AC_PATH_XTRA is called.

AM_C_PROTOTYPES
This is required when using the deprecated de-ANSI-fication feature; see Section 8.18 [ANSI], page 80. It will be removed in the next major Automake release.

AM_CONDITIONAL
This introduces an Automake conditional (see Chapter 20 [Conditionals], page 114).

AM_COND_IF
This macro allows automake to detect subsequent access within configure.ac to a conditional previously introduced with AM_CONDITIONAL, thus enabling conditional AC_CONFIG_FILES (see Section 20.1 [Usage of Conditionals], page 114).

AM_GNU_GETTEXT
This macro is required for packages that use GNU gettext (see Section 10.2 [gettext], page 89). It is distributed with gettext. If Automake sees this macro it ensures that the package meets some of gettext’s requirements.

AM_GNU_GETTEXT_INTL_SUBDIR
This macro specifies that the intl/ subdirectory is to be built, even if the AM_GNU_GETTEXT macro was invoked with a first argument of ‘external’.
AM_MAINTAINER_MODE([default-mode])

This macro adds an --enable-maintainer-mode option to configure. If this is used, automake will cause “maintainer-only” rules to be turned off by default in the generated Makefile.in, unless default-mode is ‘enable’. This macro defines the MAINTAINER_MODE conditional, which you can use in your own Makefile.am. See Section 28.2 [maintainer-mode], page 130.

AM_SUBST_NOTMAKE(var)

Prevent Automake from defining a variable var, even if it is substituted by config.status. Normally, Automake defines a make variable for each configure substitution, i.e., for each AC_SUBST([var]). This macro prevents that definition from Automake. If AC_SUBST has not been called for this variable, then AM_SUBST_NOTMAKE has no effects. Preventing variable definitions may be useful for substitution of multi-line values, where var = @value@ might yield unintended results.

m4_include

Files included by configure.ac using this macro will be detected by Automake and automatically distributed. They will also appear as dependencies in Makefile rules.

m4_include is seldom used by configure.ac authors, but can appear in aclocal.m4 when aclocal detects that some required macros come from files local to your package (as opposed to macros installed in a system-wide directory, see Section 6.3 [aclocal Invocation], page 35).

6.3 Auto-generating aclocal.m4

Automake includes a number of Autoconf macros that can be used in your package (see Section 6.4 [Macros], page 44); some of them are actually required by Automake in certain situations. These macros must be defined in your aclocal.m4; otherwise they will not be seen by autoconf.

The aclocal program will automatically generate aclocal.m4 files based on the contents of configure.ac. This provides a convenient way to get Automake-provided macros, without having to search around. The aclocal mechanism allows other packages to supply their own macros (see Section 6.3.3 [Extending aclocal], page 40). You can also use it to maintain your own set of custom macros (see Section 6.3.4 [Local Macros], page 41).

At startup, aclocal scans all the .m4 files it can find, looking for macro definitions (see Section 6.3.2 [Macro Search Path], page 37). Then it scans configure.ac. Any mention of one of the macros found in the first step causes that macro, and any macros it in turn requires, to be put into aclocal.m4.

Putting the file that contains the macro definition into aclocal.m4 is usually done by copying the entire text of this file, including unused macro definitions as well as both ‘#’ and ‘dnl’ comments. If you want to make a comment that will be completely ignored by aclocal, use ‘##’ as the comment leader.

When a file selected by aclocal is located in a subdirectory specified as a relative search path with aclocal’s -I argument, aclocal assumes the file belongs to the package and uses m4_include instead of copying it into aclocal.m4. This makes the package smaller, eases
dependency tracking, and cause the file to be distributed automatically. (See Section 6.3.4 [Local Macros], page 41, for an example.) Any macro that is found in a system-wide directory, or via an absolute search path will be copied. So use ‘-I ‘pwd’/relldir’ instead of ‘-I relldir’ whenever some relative directory should be considered outside the package.

The contents of acinclude.m4, if this file exists, are also automatically included in aclocal.m4. We recommend against using acinclude.m4 in new packages (see Section 6.3.4 [Local Macros], page 41).

While computing aclocal.m4, aclocal runs autom4te (see Section “Using Autom4te” in The Autoconf Manual) in order to trace the macros that are really used, and omit from aclocal.m4 all macros that are mentioned but otherwise unexpanded (this can happen when a macro is called conditionally). autom4te is expected to be in the PATH, just as autoconf. Its location can be overridden using the AUTOM4TE environment variable.

6.3.1 aclocal Options

aclocal accepts the following options:

--automake-acdir=dir
Look for the automake-provided macro files in dir instead of in the installation directory. This is typically used for debugging.

--system-acdir=dir
Look for the system-wide third-party macro files (and the special dirlist file) in dir instead of in the installation directory. This is typically used for debugging.

--acdir=dir
Deprecated shorthand for “--automake-acdir=dir --system-acdir=dir”. Will be removed in future aclocal versions.

--diff[=command]
Run command on M4 file that would be installed or overwritten by --install. The default command is ‘diff -u’. This option implies --install and --dry-run.

--dry-run
Do not actually overwrite (or create) aclocal.m4 and M4 files installed by --install.

--help
Print a summary of the command line options and exit.

-I dir
Add the directory dir to the list of directories searched for .m4 files.

--install
Install system-wide third-party macros into the first directory specified with ‘-I dir’ instead of copying them in the output file. Note that this will happen also if dir is an absolute path.

When this option is used, and only when this option is used, aclocal will also honor ‘#serial number’ lines that appear in macros: an M4 file is ignored if there exists another M4 file with the same basename and a greater serial number in the search path (see Section 6.3.5 [Serials], page 42).
--force
Always overwrite the output file. The default is to overwrite the output file only when really needed, i.e., when its contents changes or if one of its dependencies is younger.
This option forces the update of aclocal.m4 (or the file specified with --output below) and only this file, it has absolutely no influence on files that may need to be installed by --install.

--output=file
Cause the output to be put into file instead of aclocal.m4.

--print-ac-dir
Prints the name of the directory that aclocal will search to find third-party .m4 files. When this option is given, normal processing is suppressed. This option was used in the past by third-party packages to determine where to install .m4 macro files, but this usage is today discouraged, since it causes ‘$(prefix)’ not to be thoroughly honoured (which violates the GNU Coding Standards), and a similar semantics can be better obtained with the ACLOCAL_PATH environment variable; see Section 6.3.3 [Extending aclocal], page 40.

--verbose
Print the names of the files it examines.

--version
Print the version number of Automake and exit.

-W CATEGORY
--warnings=category
Output warnings falling in category. category can be one of:
syntax dubious syntactic constructs, underquoted macros, unused macros, etc.
unsupported unknown macros
all all the warnings, this is the default
none turn off all the warnings
error treat warnings as errors

All warnings are output by default.
The environment variable WARNINGS is honored in the same way as it is for automake (see Chapter 5 [automake Invocation], page 27).

6.3.2 Macro Search Path
By default, aclocal searches for .m4 files in the following directories, in this order:
acdir-APIVERSION
This is where the .m4 macros distributed with Automake itself are stored. APIVERSION depends on the Automake release used; for example, for Automake 1.11.x, APIVERSION = 1.11.
This directory is intended for third party .m4 files, and is configured when automake itself is built. This is @datadir@/aclocal/, which typically expands to ${prefix}/share/aclocal/. To find the compiled-in value of acdir, use the --print-ac-dir option (see Section 6.3.1 [aclocal Options], page 36).

As an example, suppose that automake-1.11.2 was configured with --prefix=/usr/local. Then, the search path would be:

1. /usr/local/share/aclocal-1.11.2/
2. /usr/local/share/aclocal/

The paths for the acdir and acdir-APIVERSION directories can be changed respectively through aclocal options --system-acdir and --automake-acdir (see Section 6.3.1 [aclocal Options], page 36). Note however that these options are only intended for use by the internal Automake test suite, or for debugging under highly unusual situations; they are not ordinarily needed by end-users.

As explained in (see Section 6.3.1 [aclocal Options], page 36), there are several options that can be used to change or extend this search path.

Modifying the Macro Search Path: ‘-I dir’

Any extra directories specified using -I options (see Section 6.3.1 [aclocal Options], page 36) are prepended to this search list. Thus, ‘aclocal -I /foo -I /bar’ results in the following search path:

1. /foo
2. /bar
3. acdir-APIVERSION
4. acdir

Modifying the Macro Search Path: dirlist

There is a third mechanism for customizing the search path. If a dirlist file exists in acdir, then that file is assumed to contain a list of directory patterns, one per line. aclocal expands these patterns to directory names, and adds them to the search list after all other directories. dirlist entries may use shell wildcards such as ‘*’, ‘?’, or [...].

For example, suppose acdir/dirlst contains the following:

```
/test1
/test2
/test3*
```

and that aclocal was called with the ‘-I /foo -I /bar’ options. Then, the search path would be:

1. /foo
2. /bar
3. acdir-APIVERSION
4. acdir
5. /test1
6. /test2
and all directories with path names starting with /test3.

If the --system-acdir=dir option is used, then aclocal will search for the dirlist file in dir; but remember the warnings above against the use of --system-acdir.

dirlist is useful in the following situation: suppose that automake version 1.11.2 is installed with --prefix=/usr by the system vendor. Thus, the default search directories are

1. /usr/share/aclocal-1.11/
2. /usr/share/aclocal/

However, suppose further that many packages have been manually installed on the system, with $prefix=/usr/local, as is typical. In that case, many of these “extra” .m4 files are in /usr/local/share/aclocal. The only way to force /usr/bin/aclocal to find these “extra” .m4 files is to always call 'aclocal -I /usr/local/share/aclocal'. This is inconvenient. With dirlist, one may create a file /usr/share/aclocal/dirlist containing only the single line

    /usr/local/share/aclocal

Now, the “default” search path on the affected system is

1. /usr/share/aclocal-1.11/
2. /usr/share/aclocal/
3. /usr/local/share/aclocal/

without the need for -I options; -I options can be reserved for project-specific needs (my-source-dir/m4/), rather than using it to work around local system-dependent tool installation directories.

Similarly, dirlist can be handy if you have installed a local copy of Automake in your account and want aclocal to look for macros installed at other places on the system.

Modifying the Macro Search Path: ACLOCAL_PATH

The fourth and last mechanism to customize the macro search path is also the simplest. Any directory included in the colon-separated environment variable ACLOCAL_PATH is added to the search path and takes precedence over system directories (including those found via dirlist), with the exception of the versioned directory acdir-APIVERSION (see Section 6.3.2 [Macro Search Path], page 37). However, directories passed via -I will take precedence over directories in ACLOCAL_PATH.

Also note that, if the --install option is used, any .m4 file containing a required macro that is found in a directory listed in ACLOCAL_PATH will be installed locally. In this case, serial numbers in .m4 are honoured too, see Section 6.3.5 [Serials], page 42.

Conversely to dirlist, ACLOCAL_PATH is useful if you are using a global copy of Automake and want aclocal to look for macros somewhere under your home directory.

Planned future incompatibilities

The order in which the directories in the macro search path are currently looked up is confusing and/or suboptimal in various aspects, and is probably going to be changed in the future Automake release. In particular, directories in ACLOCAL_PATH and acdir might end up taking precedence over acdir-APIVERSION, and directories in acdir/dirlist might end up taking precedence over acdir. This is a possible future incompatibility!
6.3.3 Writing your own aclocal macros

The aclocal program doesn’t have any built-in knowledge of any macros, so it is easy to extend it with your own macros.

This can be used by libraries that want to supply their own Autoconf macros for use by other programs. For instance, the gettext library supplies a macro AM_GNU_GETTEXT that should be used by any package using gettext. When the library is installed, it installs this macro so that aclocal will find it.

A macro file’s name should end in .m4. Such files should be installed in $(datadir)/aclocal. This is as simple as writing:

```
aclocaldir = $(datadir)/aclocal
aclocal_DATA = mymacro.m4 myothermacro.m4
```

Please do use $(datadir)/aclocal, and not something based on the result of ‘aclocal --print-ac-dir’ (see Section 28.10 [Hard-Coded Install Paths], page 143, for arguments). It might also be helpful to suggest to the user to add the $(datadir)/aclocal directory to his ACLOCAL_PATH variable (see [ACLOCAL_PATH], page 39) so that aclocal will find the .m4 files installed by your package automatically.

A file of macros should be a series of properly quoted AC_DEFUN’s (see Section “Macro Definitions” in The Autoconf Manual). The aclocal programs also understands AC_REQUIRE (see Section “Prerequisite Macros” in The Autoconf Manual), so it is safe to put each macro in a separate file. Each file should have no side effects but macro definitions. Especially, any call to AC_PREREQ should be done inside the defined macro, not at the beginning of the file.

Starting with Automake 1.8, aclocal will warn about all underquoted calls to AC_DEFUN. We realize this will annoy a lot of people, because aclocal was not so strict in the past and many third party macros are underquoted; and we have to apologize for this temporary inconvenience. The reason we have to be stricter is that a future implementation of aclocal (see Section 6.3.6 [Future of aclocal], page 44) will have to temporarily include all these third party .m4 files, maybe several times, including even files that are not actually needed. Doing so should alleviate many problems of the current implementation, however it requires a stricter style from the macro authors. Hopefully it is easy to revise the existing macros. For instance,

```
# bad style
AC_PREREQ(2.57)
AC_DEFUN(AX_FOOBAR,
    [AC_REQUIRE([AX_SOMETHING])dnl
    AX_FOO
    AX_BAR
])
```

should be rewritten as

```
AC_DEFUN([AX_FOOBAR],
    [AC_PREREQ([2.57])dnl
    AC_REQUIRE([AX_SOMETHING])dnl
    AX_FOO
    AX_BAR
)
Wrapping the \texttt{AC_PREREQ} call inside the macro ensures that Autoconf 2.57 will not be required if \texttt{AX_FOOBAR} is not actually used. Most importantly, quoting the first argument of \texttt{AC_DEFUN} allows the macro to be redefined or included twice (otherwise this first argument would be expanded during the second definition). For consistency we like to quote even arguments such as 2.57 that do not require it.

If you have been directed here by the \texttt{aclocal} diagnostic but are not the maintainer of the implicated macro, you will want to contact the maintainer of that macro. Please make sure you have the latest version of the macro and that the problem hasn’t already been reported before doing so: people tend to work faster when they aren’t flooded by mails.

Another situation where \texttt{aclocal} is commonly used is to manage macros that are used locally by the package, Section 6.3.4 [Local Macros], page 41.

### 6.3.4 Handling Local Macros

Feature tests offered by Autoconf do not cover all needs. People often have to supplement existing tests with their own macros, or with third-party macros.

There are two ways to organize custom macros in a package.

The first possibility (the historical practice) is to list all your macros in \texttt{acinclude.m4}. This file will be included in \texttt{aclocal.m4} when you run \texttt{aclocal}, and its macro(s) will henceforth be visible to \texttt{autoconf}. However if it contains numerous macros, it will rapidly become difficult to maintain, and it will be almost impossible to share macros between packages.

The second possibility, which we do recommend, is to write each macro in its own file and gather all these files in a directory. This directory is usually called \texttt{m4/}. To build \texttt{aclocal.m4}, one should therefore instruct \texttt{aclocal} to scan \texttt{m4/}. From the command line, this is done with \texttt{`aclocal -I m4'}. The top-level \texttt{Makefile.am} should also be updated to define

\begin{verbatim}
ACLOCAL_AMFLAGS = -I m4
\end{verbatim}

\texttt{ACLOCAL_AMFLAGS} contains options to pass to \texttt{aclocal} when \texttt{aclocal.m4} is to be rebuilt by \texttt{make}. This line is also used by \texttt{autoreconf} (see Section “Using \texttt{autoreconf} to Update \texttt{configure} Scripts” in \textit{The Autoconf Manual}) to run \texttt{aclocal} with suitable options, or by \texttt{autopoint} (see Section “Invoking the \texttt{autopoint} Program” in \textit{GNU gettext tools}) and \texttt{gettextize} (see Section “Invoking the \texttt{gettextize} Program” in \textit{GNU gettext tools}) to locate the place where Gettext’s macros should be installed. So even if you do not really care about the rebuild rules, you should define \texttt{ACLOCAL_AMFLAGS}.

When \texttt{`aclocal -I m4'} is run, it will build an \texttt{aclocal.m4} that \texttt{m4_includes} any file from \texttt{m4/} that defines a required macro. Macros not found locally will still be searched in system-wide directories, as explained in Section 6.3.2 [Macro Search Path], page 37.

Custom macros should be distributed for the same reason that \texttt{configure.ac} is: so that other people have all the sources of your package if they want to work on it. Actually, this distribution happens automatically because all \texttt{m4_included} files are distributed.

However there is no consensus on the distribution of third-party macros that your package may use. Many libraries install their own macro in the system-wide \texttt{aclocal} directory (see Section 6.3.3 [Extending \texttt{aclocal}], page 40). For instance, Guile ships with a file called
guile.m4 that contains the macro GUILE_FLAGS that can be used to define setup compiler and linker flags appropriate for using Guile. Using GUILE_FLAGS in configure.ac will cause aclocal to copy guile.m4 into aclocal.m4, but as guile.m4 is not part of the project, it will not be distributed. Technically, that means a user who needs to rebuild aclocal.m4 will have to install Guile first. This is probably OK, if Guile already is a requirement to build the package. However, if Guile is only an optional feature, or if your package might run on architectures where Guile cannot be installed, this requirement will hinder development. An easy solution is to copy such third-party macros in your local m4/ directory so they get distributed.

Since Automake 1.10, aclocal offers an option to copy these system-wide third-party macros in your local macro directory, solving the above problem. Simply use:

```bash
ACLOCAL_AMFLAGS = -I m4 --install
```

With this setup, system-wide macros will be copied to m4/ the first time you run autoreconf. Then the locally installed macros will have precedence over the system-wide installed macros each time aclocal is run again.

One reason why you should keep --install in the flags even after the first run is that when you later edit configure.ac and depend on a new macro, this macro will be installed in your m4/ automatically. Another one is that serial numbers (see Section 6.3.5 [Serials], page 42) can be used to update the macros in your source tree automatically when new system-wide versions are installed. A serial number should be a single line of the form

```bash
#serial nnn
```

where nnn contains only digits and dots. It should appear in the M4 file before any macro definition. It is a good practice to maintain a serial number for each macro you distribute, even if you do not use the --install option of aclocal: this allows other people to use it.

### 6.3.5 Serial Numbers

Because third-party macros defined in *.m4 files are naturally shared between multiple projects, some people like to version them. This makes it easier to tell which of two M4 files is newer. Since at least 1996, the tradition is to use a ‘#serial’ line for this.

A serial number should be a single line of the form

```bash
# serial version
```

where version is a version number containing only digits and dots. Usually people use a single integer, and they increment it each time they change the macro (hence the name of “serial”). Such a line should appear in the M4 file before any macro definition.

The ‘#’ must be the first character on the line, and it is OK to have extra words after the version, as in

```bash
#serial version garbage
```

Normally these serial numbers are completely ignored by aclocal and autoconf, like any genuine comment. However when using aclocal’s --install feature, these serial numbers will modify the way aclocal selects the macros to install in the package: if two files with the same basename exist in your search path, and if at least one of them uses a ‘#serial’ line, aclocal will ignore the file that has the older ‘#serial’ line (or the file that has none).

Note that a serial number applies to a whole M4 file, not to any macro it contains. A file can contains multiple macros, but only one serial.
Here is a use case that illustrates the use of --install and its interaction with serial numbers. Let’s assume we maintain a package called MyPackage, the configure.ac of which requires a third-party macro AX_THIRD_PARTY defined in /usr/share/aclocal/thirdparty.m4 as follows:

```plaintext
# serial 1
AC_DEFUN([AX_THIRD_PARTY], [...])
```

MyPackage uses an m4/ directory to store local macros as explained in Section 6.3.4 [Local Macros], page 41, and has

```
ACLOCAL_AMFLAGS = -I m4 --install
```
in its top-level Makefile.am.

Initially the m4/ directory is empty. The first time we run autoreconf, it will fetch the options to pass to aclocal in Makefile.am, and run ‘aclocal -I m4 --install’. aclocal will notice that

- configure.ac uses AX_THIRD_PARTY
- No local macros define AX_THIRD_PARTY
- /usr/share/aclocal/thirdparty.m4 defines AX_THIRD_PARTY with serial 1.

Because /usr/share/aclocal/thirdparty.m4 is a system-wide macro and aclocal was given the --install option, it will copy this file in m4/thirdparty.m4, and output an aclocal.m4 that contains ‘m4_include([m4/thirdparty.m4])’.

The next time ‘aclocal -I m4 --install’ is run (either via autoreconf, by hand, or from the Makefile rebuild rules) something different happens. aclocal notices that

- configure.ac uses AX_THIRD_PARTY
- m4/thirdparty.m4 defines AX_THIRD_PARTY with serial 1.
- /usr/share/aclocal/thirdparty.m4 defines AX_THIRD_PARTY with serial 1.

Because both files have the same serial number, aclocal uses the first it found in its search path order (see Section 6.3.2 [Macro Search Path], page 37). aclocal therefore ignores /usr/share/aclocal/thirdparty.m4 and outputs an aclocal.m4 that contains ‘m4_include([m4/thirdparty.m4])’.

Local directories specified with -I are always searched before system-wide directories, so a local file will always be preferred to the system-wide file in case of equal serial numbers.

Now suppose the system-wide third-party macro is changed. This can happen if the package installing this macro is updated. Let’s suppose the new macro has serial number 2. The next time ‘aclocal -I m4 --install’ is run the situation is the following:

- configure.ac uses AX_THIRD_PARTY
- m4/thirdparty.m4 defines AX_THIRD_PARTY with serial 1.
- /usr/share/aclocal/thirdparty.m4 defines AX_THIRD_PARTY with serial 2.

When aclocal sees a greater serial number, it immediately forgets anything it knows from files that have the same basename and a smaller serial number. So after it has found /usr/share/aclocal/thirdparty.m4 with serial 2, aclocal will proceed as if it had never seen m4/thirdparty.m4. This brings us back to a situation similar to that at the beginning of our example, where no local file defined the macro. aclocal will install the new version.
of the macro in `m4/thirdparty.m4`, in this case overriding the old version. MyPackage just had its macro updated as a side effect of running `aclocal`.

If you are leery of letting `aclocal` update your local macro, you can run `aclocal -I m4 --diff` to review the changes `aclocal -I m4 --install` would perform on these macros.

Finally, note that the `--force` option of `aclocal` has absolutely no effect on the files installed by `--install`. For instance, if you have modified your local macros, do not expect `--install --force` to replace the local macros by their system-wide versions. If you want to do so, simply erase the local macros you want to revert, and run `aclocal -I m4 --install`.

6.3.6 The Future of aclocal

`aclocal` is expected to disappear. This feature really should not be offered by Automake. Automake should focus on generating `Makefile`s; dealing with M4 macros really is Autoconf’s job. The fact that some people install Automake just to use `aclocal`, but do not use `automake` otherwise is an indication of how that feature is misplaced.

The new implementation will probably be done slightly differently. For instance, it could enforce the `m4/-style layout discussed in Section 6.3.4 [Local Macros], page 41.

We have no idea when and how this will happen. This has been discussed several times in the past, but someone still has to commit to that non-trivial task.

From the user point of view, `aclocal`’s removal might turn out to be painful. There is a simple precaution that you may take to make that switch more seamless: never call `aclocal` yourself. Keep this guy under the exclusive control of `autoreconf` and Automake’s rebuild rules. Hopefully you won’t need to worry about things breaking, when `aclocal` disappears, because everything will have been taken care of. If otherwise you used to call `aclocal` directly yourself or from some script, you will quickly notice the change.

Many packages come with a script called `bootstrap.sh` or `autogen.sh`, that will just call `aclocal`, `libtoolize`, `gettextize` or `autopoint`, `autoconf`, `autoheader`, and `automake` in the right order. Actually this is precisely what `autoreconf` can do for you. If your package has such a `bootstrap.sh` or `autogen.sh` script, consider using `autoreconf`. That should simplify its logic a lot (less things to maintain, yun!), it’s even likely you will not need the script anymore, and more to the point you will not call `aclocal` directly anymore.

For the time being, third-party packages should continue to install public macros into `/usr/share/aclocal/`. If `aclocal` is replaced by another tool it might make sense to rename the directory, but supporting `/usr/share/aclocal/` for backward compatibility should be really easy provided all macros are properly written (see Section 6.3.3 [Extending aclocal], page 40).

6.4 Autoconf macros supplied with Automake

Automake ships with several Autoconf macros that you can use from your `configure.ac`. When you use one of them it will be included by `aclocal` in `aclocal.m4`.

6.4.1 Public Macros

`AM_ENABLE_MULTILIB`

This is used when a “multilib” library is being built. Please be aware that multilib support will be removed from the Automake core in the next major
release, and then this macro will go away as well (even if a “frozen” version of
will remain available in the contrib/ directory of the Automake distribution).
The first optional argument is the name of the Makefile being generated; it
defaults to ‘Makefile’. The second optional argument is used to find the top
source directory; it defaults to the empty string (generally this should not be
used unless you are familiar with the internals). See Section 18.3 [Multilibs],
page 113.

AM_INIT_AUTOMAKE([OPTIONS])
AM_INIT_AUTOMAKE(PACKAGE, VERSION, [NO-DEFINE])

Runs many macros required for proper operation of the generated Makefiles.
This macro has two forms, the first of which is preferred. In this form, AM_INIT_ AUTOMAKE is called with a single argument: a space-separated list of Automake options that should be applied to every Makefile.am in the tree. The effect is as if each option were listed in AUTOMAKE_OPTIONS (see Chapter 17 [Options],
page 107).
The second, deprecated, form of AM_INIT_AUTOMAKE has two required argu-
ments: the package and the version number. This form is obsolete because the
package and version can be obtained from Autoconf’s AC_INIT macro (which
itself has an old and a new form).
If your configure.ac has:

AC_INIT([src/foo.c])
AM_INIT_AUTOMAKE([mumble], [1.5])

you can modernize it as follows:

AC_INIT([mumble], [1.5])
AC_CONFIG_SRCDIR([src/foo.c])
AM_INIT_AUTOMAKE

Note that if you’re upgrading your configure.ac from an earlier version of
Automake, it is not always correct to simply move the package and version
arguments from AM_INIT_AUTOMAKE directly to AC_INIT, as in the example
above. The first argument to AC_INIT should be the name of your package
(e.g., ‘GNU Automake’), not the tarball name (e.g., ‘automake’) that you used
to pass to AM_INIT_AUTOMAKE. Autoconf tries to derive a tarball name from
the package name, which should work for most but not all package names. (If
it doesn’t work for yours, you can use the four-argument form of AC_INIT to
provide the tarball name explicitly).
By default this macro AC_DEFINE’s PACKAGE and VERSION. This can be avoided
by passing the no-define option, as in:

AM_INIT_AUTOMAKE([gnits 1.5 no-define dist-bzip2])
or by passing a third non-empty argument to the obsolete form.

AM_PATH_LISPDIR

Searches for the program emacs, and, if found, sets the output variable lispdir
to the full path to Emacs’ site-lisp directory.
Note that this test assumes the emacs found to be a version that supports
Emacs Lisp (such as GNU Emacs or XEmacs). Other emacs can cause this
test to hang (some, like old versions of MicroEmacs, start up in interactive mode, requiring \texttt{C-x C-c} to exit, which is hardly obvious for a non-emacs user). In most cases, however, you should be able to use \texttt{C-c} to kill the test. In order to avoid problems, you can set \texttt{EMACS} to “no” in the environment, or use the \texttt{--with-lispdir} option to \texttt{configure} to explicitly set the correct path (if you’re sure you have an \texttt{emacs} that supports Emacs Lisp).

\texttt{AM_PROG_AR([act-if-fail])}

You must use this macro when you use the archiver in your project, if you want support for unusual archivers such as Microsoft \texttt{lib}. The content of the optional argument is executed if the archiver interface is not recognized; the default action is to abort configure with an error message.

\texttt{AM_PROG_AS}

Use this macro when you have assembly code in your project. This will choose the assembler for you (by default the C compiler) and set \texttt{CCAS}, and will also set \texttt{CCASFLAGS} if required.

\texttt{AM_PROG_CC_C_O}

This is like \texttt{AC_PROG_CC_C_O}, but it generates its results in the manner required by Automake. You must use this instead of \texttt{AC_PROG_CC_C_O} when you need this functionality, that is, when using per-target flags or subdir-objects with C sources.

\texttt{AM_PROG_LEX}

Like \texttt{AC_PROG_LEX} (see Section “Particular Program Checks” in \textit{The Autoconf Manual}), but uses the \texttt{missing} script on systems that do not have \texttt{lex}. HP-UX 10 is one such system.

\texttt{AM_PROG_GCJ}

This macro finds the \texttt{gcj} program or causes an error. It sets \texttt{GCJ} and \texttt{GCJFLAGS}. \texttt{gcj} is the Java front-end to the GNU Compiler Collection.

\texttt{AM_PROG_UPC([compiler-search-list])}

Find a compiler for Unified Parallel C and define the \texttt{UPC} variable. The default \texttt{compiler-search-list} is ‘\texttt{upcc upc}’. This macro will abort \texttt{configure} if no Unified Parallel C compiler is found.

\texttt{AM_SILENT_RULES}

Enable the machinery for less verbose build output (see Chapter 17 [Options], page 107).

\texttt{AM_WITH_Dmalloc}

Add support for the Dmalloc package (\url{http://dmalloc.com/}). If the user runs \texttt{configure} with \texttt{--with-dmalloc}, then define \texttt{WITH_Dmalloc} and add \texttt{-ldmalloc} to \texttt{LIBS}.

### 6.4.2 Obsolete Macros

Although using some of the following macros was required in past releases, you should not use any of them in new code. Running \texttt{autoupdate} should adjust your \texttt{configure.ac} automatically (see Section “Using \texttt{autoupdate} to Modernize \texttt{configure.ac}” in \textit{The Autoconf Manual}).
AM_C_PROTOTYPES
Check to see if function prototypes are understood by the compiler. If so, define ‘PROTOTYPES’ and set the output variables U and ANSI2KNR to the empty string. Otherwise, set U to ‘_’ and ANSI2KNR to ‘./ansi2knr’. Automake used these values to implement the deprecated de-ANSI-fication feature; however, support for that feature will be removed in the next major Automake release, and then these macros and variables will go away as well.

AM_CONFIG_HEADER
Automake will generate rules to automatically regenerate the config header. This obsolete macro is a synonym of AC_CONFIG_HEADERS today (see Section 6.2 [Optional], page 32).

AM_HEADER_TIOCGWINSZ_NEEDS_SYS_IOCTL
If the use of TIOCGWINSZ requires <sys/ioctl.h>, then define GWINSZ_IN_SYS_IOCTL. Otherwise TIOCGWINSZ can be found in <termios.h>. This macro is obsolete, you should use Autoconf’s AC_HEADER_TIOCGWINSZ instead.

AM_PROG_MKDIR_P
From Automake 1.8 to 1.9.6 this macro used to define the output variable mkdir_p to one of mkdir -p, install-sh -d, or mkinstalldirs. Nowadays Autoconf provides a similar functionality with AC_PROG_MKDIR_P (see Section “Particular Program Checks” in The Autoconf Manual), however this defines the output variable MKDIR_P instead. Therefore AM_PROG_MKDIR_P has been rewritten as a thin wrapper around AC_PROG_MKDIR_P to define mkdir_p to the same value as MKDIR_P for backward compatibility.

If you are using Automake, there is normally no reason to call this macro, because AM_INIT_AUTOMAKE already does so. However, make sure that the custom rules in your Makefiles use $(MKDIR_P) and not $(mkdir_p). Even if both variables still work, the latter should be considered obsolete.

If you are not using Automake, please call AC_PROG_MKDIR_P instead of AM_PROG_MKDIR_P.

AM_SYS_POSIX_TERMIOS
Check to see if POSIX termios headers and functions are available on the system. If so, set the shell variable am_cv_sys_posix_termios to ‘yes’. If not, set the variable to ‘no’. This macro is obsolete, you should use Autoconf’s AC_SYS_POSIX_TERMIOS instead.

AM_WITH_REGEX
Adds --with-regex to the configure command line. If specified (the default), then the ‘regex’ regular expression library is used, regex.o is put into LIBOBSJS, and WITH_REGEX is defined. If --without-regex is given, then the ‘rx’ regular expression library is used, and rx.o is put into LIBOBSJS. This macro is obsolete now (since ‘rx’ doesn’t seem to be maintained), and will be removed the next major version of Automake. Consider using gnulib if you need regex functionality.
6.4.3 Private Macros

The following macros are private macros you should not call directly. They are called by the other public macros when appropriate. Do not rely on them, as they might be changed in a future version. Consider them as implementation details; or better, do not consider them at all: skip this section!

\_AM\_DEPENDENCIES
AM\_SET\_DEPDIR
AM\_DEP\_TRACK
AM\_OUTPUT\_DEPENDENCY\_COMMANDS

These macros are used to implement Automake’s automatic dependency tracking scheme. They are called automatically by Automake when required, and there should be no need to invoke them manually.

AM\_MAKE\_INCLUDE

This macro is used to discover how the user’s make handles include statements. This macro is automatically invoked when needed; there should be no need to invoke it manually.

AM\_PROG\_INSTALL\_STRIP

This is used to find a version of install that can be used to strip a program at installation time. This macro is automatically included when required.

AM\_SANITY\_CHECK

This checks to make sure that a file created in the build directory is newer than a file in the source directory. This can fail on systems where the clock is set incorrectly. This macro is automatically run from AM\_INIT\_AUTOMAKE.

7 Directories

For simple projects that distribute all files in the same directory it is enough to have a single Makefile.am that builds everything in place.

In larger projects it is common to organize files in different directories, in a tree. For instance one directory per program, per library or per module. The traditional approach is to build these subdirectories recursively: each directory contains its Makefile (generated from Makefile.am), and when make is run from the top level directory it enters each subdirectory in turn to build its contents.

7.1 Recursing subdirectories

In packages with subdirectories, the top level Makefile.am must tell Automake which subdirectories are to be built. This is done via the SUBDIRS variable.

The SUBDIRS variable holds a list of subdirectories in which building of various sorts can occur. The rules for many targets (e.g., all) in the generated Makefile will run commands both locally and in all specified subdirectories. Note that the directories listed in SUBDIRS are not required to contain Makefile.ams; only Makefiles (after configuration). This allows inclusion of libraries from packages that do not use Automake (such as gettext; see also Section 24.2 [Third-Party Makefiles], page 123).
In packages that use subdirectories, the top-level `Makefile.am` is often very short. For instance, here is the `Makefile.am` from the GNU Hello distribution:

```
EXTRA_DIST = BUGS ChangeLog.0 README-alpha
SUBDIRS = doc intl po src tests
```

When Automake invokes `make` in a subdirectory, it uses the value of the `MAKE` variable. It passes the value of the variable `AM_MAKEFLAGS` to the `make` invocation; this can be set in `Makefile.am` if there are flags you must always pass to `make`.

The directories mentioned in `SUBDIRS` are usually direct children of the current directory, each subdirectory containing its own `Makefile.am` with a `SUBDIRS` pointing to deeper subdirectories. Automake can be used to construct packages of arbitrary depth this way.

By default, Automake generates `Makefiles` that work depth-first in postfix order: the subdirectories are built before the current directory. However, it is possible to change this ordering. You can do this by putting ‘.’ into `SUBDIRS`. For instance, putting ‘.’ first will cause a prefix ordering of directories.

Using

```
SUBDIRS = lib src . test
```

will cause `lib/` to be built before `src/`, then the current directory will be built, finally the `test/` directory will be built. It is customary to arrange test directories to be built after everything else since they are meant to test what has been constructed.

All `clean` rules are run in reverse order of build rules.

### 7.2 Conditional Subdirectories

It is possible to define the `SUBDIRS` variable conditionally if, like in the case of GNU Inetutils, you want to only build a subset of the entire package.

To illustrate how this works, let’s assume we have two directories `src/` and `opt/`. `src/` should always be built, but we want to decide in `configure` whether `opt/` will be built or not. (For this example we will assume that `opt/` should be built when the variable `$want_opt` was set to ‘yes’.)

Running `make` should thus recurse into `src/` always, and then maybe in `opt/`.

However ‘`make dist`’ should always recurse into both `src/` and `opt/`. Because `opt/` should be distributed even if it is not needed in the current configuration. This means `opt/Makefile` should be created `unconditionally`.

There are two ways to setup a project like this. You can use Automake conditionals (see Chapter 20 [Conditionals], page 114) or use Autoconf `AC_SUBST` variables (see Section “Setting Output Variables” in The Autoconf Manual). Using Automake conditionals is the preferred solution. Before we illustrate these two possibilities, let’s introduce `DIST_SUBDIRS`.

#### 7.2.1 SUBDIRS vs. DIST_SUBDIRS

Automake considers two sets of directories, defined by the variables `SUBDIRS` and `DIST_SUBDIRS`.

`SUBDIRS` contains the subdirectories of the current directory that must be built (see Section 7.1 [Subdirectories], page 48). It must be defined manually; Automake will never
guess a directory is to be built. As we will see in the next two sections, it is possible to define it conditionally so that some directory will be omitted from the build.

DIST_SUBDIRS is used in rules that need to recurse in all directories, even those that have been conditionally left out of the build. Recall our example where we may not want to build subdirectory opt/, but yet we want to distribute it? This is where DIST_SUBDIRS comes into play: ‘opt’ may not appear in SUBDIRS, but it must appear in DIST_SUBDIRS.

Precisely, DIST_SUBDIRS is used by ‘make maintainer-clean’, ‘make distclean’ and ‘make dist’. All other recursive rules use SUBDIRS.

If SUBDIRS is defined conditionally using Automake conditionals, Automake will define DIST_SUBDIRS automatically from the possible values of SUBDIRS in all conditions.

If SUBDIRS contains AC_SUBST variables, DIST_SUBDIRS will not be defined correctly because Automake does not know the possible values of these variables. In this case DIST_SUBDIRS needs to be defined manually.

7.2.2 Subdirectories with AM_CONDITIONAL

configure should output the Makefile for each directory and define a condition into which opt/ should be built.

...  
AM_CONDITIONAL([COND_OPT], [test "$want_opt" = yes])  
AC_CONFIG_FILES([Makefile src/Makefile opt/Makefile])  
...

Then SUBDIRS can be defined in the top-level Makefile.am as follows.

if COND_OPT  
  MAYBE_OPT = opt  
endif  
SUBDIRS = src $(MAYBE_OPT)

As you can see, running make will rightly recurse into src/ and maybe opt/.

As you can’t see, running ‘make dist’ will recurse into both src/ and opt/ directories because ‘make dist’, unlike ‘make all’, doesn’t use the SUBDIRS variable. It uses the DIST_SUBDIRS variable.

In this case Automake will define ‘DIST_SUBDIRS = src opt’ automatically because it knows that MAYBE_OPT can contain ‘opt’ in some condition.

7.2.3 Subdirectories with AC_SUBST

Another possibility is to define MAYBE_OPT from ./configure using AC_SUBST:

...  
if test "$want_opt" = yes; then  
  MAYBE_OPT=opt  
else  
  MAYBE_OPT=  
fi  
AC_SUBST([MAYBE_OPT])  
AC_CONFIG_FILES([Makefile src/Makefile opt/Makefile])  
...
In this case the top-level `Makefile.am` should look as follows.

```makefile
SUBDIRS = src $(MAYBE_OPT)
DIST_SUBDIRS = src opt
```

The drawback is that since Automake cannot guess what the possible values of `MAYBE_OPT` are, it is necessary to define `DIST_SUBDIRS`.

### 7.2.4 Unconfigured Subdirectories

The semantics of `DIST_SUBDIRS` are often misunderstood by some users that try to `configure` and `build` subdirectories conditionally. Here by configuring we mean creating the `Makefile` (it might also involve running a nested `configure` script: this is a costly operation that explains why people want to do it conditionally, but only the `Makefile` is relevant to the discussion).

The above examples all assume that every `Makefile` is created, even in directories that are not going to be built. The simple reason is that we want `make dist` to distribute even the directories that are not being built (e.g., platform-dependent code), hence `make dist` must recurse into the subdirectory, hence this directory must be configured and appear in `DIST_SUBDIRS`.

Building packages that do not configure every subdirectory is a tricky business, and we do not recommend it to the novice as it is easy to produce an incomplete tarball by mistake. We will not discuss this topic in depth here, yet for the adventurous here are a few rules to remember.

- **SUBDIRS** should always be a subset of **DIST_SUBDIRS**.
  It makes little sense to have a directory in **SUBDIRS** that is not in **DIST_SUBDIRS**. Think of the former as a way to tell which directories listed in the latter should be built.
- Any directory listed in **DIST_SUBDIRS** and **SUBDIRS** must be configured.
  I.e., the `Makefile` must exist or the recursive `make` rules will not be able to process the directory.
- Any configured directory must be listed in **DIST_SUBDIRS**.
  So that the cleaning rules remove the generated `Makefiles`. It would be correct to see **DIST_SUBDIRS** as a variable that lists all the directories that have been configured.

In order to prevent recursion in some unconfigured directory you must therefore ensure that this directory does not appear in **DIST_SUBDIRS** (and **SUBDIRS**). For instance, if you define **SUBDIRS** conditionally using `AC_SUBST` and do not define **DIST_SUBDIRS** explicitly, it will be default to `\$\$(SUBDIRS)`; another possibility is to force `DIST_SUBDIRS = \$\$(SUBDIRS)`.

Of course, directories that are omitted from **DIST_SUBDIRS** will not be distributed unless you make other arrangements for this to happen (for instance, always running `make dist` in a configuration where all directories are known to appear in **DIST_SUBDIRS**; or writing a `dist-hook` target to distribute these directories).

In few packages, unconfigured directories are not even expected to be distributed. Although these packages do not require the aforementioned extra arrangements, there is another pitfall. If the name of a directory appears in **SUBDIRS** or **DIST_SUBDIRS**, automake
will make sure the directory exists. Consequently automake cannot be run on such a distribution when one directory has been omitted. One way to avoid this check is to use the AC_SUBST method to declare conditional directories; since automake does not know the values of AC_SUBST variables it cannot ensure the corresponding directory exists.

7.3 An Alternative Approach to Subdirectories

If you’ve ever read Peter Miller’s excellent paper, Recursive Make Considered Harmful (http://miller.emu.id.au/pmiller/books/rmch/), the preceding sections on the use of subdirectories will probably come as unwelcome advice. For those who haven’t read the paper, Miller’s main thesis is that recursive make invocations are both slow and error-prone.

Automake provides sufficient cross-directory support\(^3\) to enable you to write a single Makefile.am for a complex multi-directory package.

By default an installable file specified in a subdirectory will have its directory name stripped before installation. For instance, in this example, the header file will be installed as $(includedir)/stdio.h:

```
include_HEADERS = inc/stdio.h
```

However, the ‘nobase_’ prefix can be used to circumvent this path stripping. In this example, the header file will be installed as $(includedir)/sys/types.h:

```
 nobase_include_HEADERS = sys/types.h
```

‘nobase_’ should be specified first when used in conjunction with either ‘dist_’ or ‘nodist_’ (see Section 14.2 [Fine-grained Distribution Control], page 99). For instance:

```
 nobase_dist_pkgdata_DATA = images/vortex.pgm sounds/whirl.ogg
```

Finally, note that a variable using the ‘nobase_’ prefix can often be replaced by several variables, one for each destination directory (see Section 3.3 [Uniform], page 20). For instance, the last example could be rewritten as follows:

```
imagesdir = $(pkgdatadir)/images
soundsdir = $(pkgdatadir)/sounds
dist_images_DATA = images/vortex.pgm
dist_sounds_DATA = sounds/whirl.ogg
```

This latter syntax makes it possible to change one destination directory without changing the layout of the source tree.

Currently, ‘nobase_*_LTLIBRARIES’ are the only exception to this rule, in that there is no particular installation order guarantee for an otherwise equivalent set of variables without ‘nobase_’ prefix.

7.4 Nesting Packages

In the GNU Build System, packages can be nested to arbitrary depth. This means that a package can embed other packages with their own configure, Makefiles, etc.

These other packages should just appear as subdirectories of their parent package. They must be listed in SUBDIRS like other ordinary directories. However the subpackage’s

\(^3\) We believe. This work is new and there are probably warts. See Chapter 1 [Introduction], page 1, for information on reporting bugs.
Makefiles should be output by its own configure script, not by the parent’s configure. This is achieved using the AC_CONFIG_SUBDIRS Autoconf macro (see Section “Configuring Other Packages in Subdirectories” in The Autoconf Manual).

Here is an example package for an arm program that links with a hand library that is a nested package in subdirectory hand/.

**arm**’s configure.ac:

```c
AC_INIT([arm], [1.0])
AC_CONFIG_AUX_DIR([.])
AM_INIT_AUTOMAKE
AC_PROG_CC
AC_CONFIG_FILES([Makefile])
# Call hand's ./configure script recursively.
AC_CONFIG_SUBDIRS([hand])
AC_OUTPUT
```

**arm**’s Makefile.am:

```c
# Build the library in the hand subdirectory first.
SUBDIRS = hand

# Include hand's header when compiling this directory.
AM_CPPFLAGS = -I$(srcdir)/hand

bin_PROGRAMS = arm
arm_SOURCES = arm.c
# link with the hand library.
arm_LDADD = hand/libhand.a
```

Now here is hand’s hand/configure.ac:

```c
AC_INIT([hand], [1.2])
AC_CONFIG_AUX_DIR([.])
AM_INIT_AUTOMAKE
AC_PROG_CC
AM_PROG_AR
AC_PROG_RANLIB
AC_CONFIG_FILES([Makefile])
AC_OUTPUT
```

and its hand/Makefile.am:

```c
lib_LIBRARIES = libhand.a
libhand_a_SOURCES = hand.c
```

When `make dist` is run from the top-level directory it will create an archive `arm-1.0.tar.gz` that contains the arm code as well as the hand subdirectory. This package can be built and installed like any ordinary package, with the usual ‘./configure && make && make install’ sequence (the hand subpackage will be built and installed by the process).

When ‘make dist’ is run from the hand directory, it will create a self-contained `hand-1.2.tar.gz` archive. So although it appears to be embedded in another package, it can still be used separately.
The purpose of the `AC_CONFIG_AUX_DIR([.])` instruction is to force Automake and Autoconf to search for auxiliary scripts in the current directory. For instance, this means that there will be two copies of `install-sh`: one in the top-level of the `arm` package, and another one in the `hand/` subdirectory for the `hand` package.

The historical default is to search for these auxiliary scripts in the parent directory and the grandparent directory. So if the `AC_CONFIG_AUX_DIR([.])` line was removed from `hand/configure.ac`, that subpackage would share the auxiliary script of the `arm` package. This may look like a gain in size (a few kilobytes), but it is actually a loss of modularity as the `hand` subpackage is no longer self-contained (`make dist` in the subdirectory will not work anymore).

Packages that do not use Automake need more work to be integrated this way. See Section 24.2 [Third-Party Makefiles], page 123.

## 8 Building Programs and Libraries

A large part of Automake’s functionality is dedicated to making it easy to build programs and libraries.

### 8.1 Building a program

In order to build a program, you need to tell Automake which sources are part of it, and which libraries it should be linked with.

This section also covers conditional compilation of sources or programs. Most of the comments about these also apply to libraries (see Section 8.2 [A Library], page 58) and `libtool` libraries (see Section 8.3 [A Shared Library], page 59).

#### 8.1.1 Defining program sources

In a directory containing source that gets built into a program (as opposed to a library or a script), the `PROGRAMS` primary is used. Programs can be installed in `bindir`, `sbindir`, `libexecdir`, `pkglibexecdir`, or not at all (`noinst_`). They can also be built only for `make check`, in which case the prefix is `check_`.

For instance:

```
bin_PROGRAMS = hello
```

In this simple case, the resulting `Makefile.in` will contain code to generate a program named `hello`.

Associated with each program are several assisting variables that are named after the program. These variables are all optional, and have reasonable defaults. Each variable, its use, and default is spelled out below; we use the “hello” example throughout.

The variable `hello_SOURCES` is used to specify which source files get built into an executable:

```
hello_SOURCES = hello.c version.c getopt.c getopt1.c getopt.h system.h
```

This causes each mentioned `.c` file to be compiled into the corresponding `.o`. Then all are linked to produce `hello`.
If hello_SOURCES is not specified, then it defaults to the single file hello.c (see Section 8.5 [Default _SOURCES], page 69).

Multiple programs can be built in a single directory. Multiple programs can share a single source file, which must be listed in each _SOURCES definition.

Header files listed in a _SOURCES definition will be included in the distribution but otherwise ignored. In case it isn’t obvious, you should not include the header file generated by configure in a _SOURCES variable; this file should not be distributed. Lex (.l) and Yacc (.y) files can also be listed; see Section 8.8 [Yacc and Lex], page 72.

8.1.2 Linking the program

If you need to link against libraries that are not found by configure, you can use LDADD to do so. This variable is used to specify additional objects or libraries to link with; it is inappropriate for specifying specific linker flags, you should use AM_LDFLAGS for this purpose.

Sometimes, multiple programs are built in one directory but do not share the same link-time requirements. In this case, you can use the prog_LDADD variable (where prog is the name of the program as it appears in some _PROGRAMS variable, and usually written in lowercase) to override LDADD. If this variable exists for a given program, then that program is not linked using LDADD.

For instance, in GNU cpio, pax, cpio and mt are linked against the library libcpio.a. However, rmt is built in the same directory, and has no such link requirement. Also, mt and rmt are only built on certain architectures. Here is what cpio’s src/Makefile.am looks like (abridged):

```makefile
bin_PROGRAMS = cpio pax $(MT)
libexec_PROGRAMS = $(RMT)
EXTRA_PROGRAMS = mt rmt
LDADD = ../lib/libcpio.a $(INTLLIBS)
rmt_LDADD =

cpio_SOURCES = ...
pax_SOURCES = ...
mt_SOURCES = ...
rmt_SOURCES = ...
```

prog_LDADD is inappropriate for passing program-specific linker flags (except for -l, -L, -dlopen and -dlpreopen). So, use the prog_LDFLAGS variable for this purpose.

It is also occasionally useful to have a program depend on some other target that is not actually part of that program. This can be done using either the prog_DEPENDENCIES or the EXTRA_prog_DEPENDENCIES variable. Each program depends on the contents both variables, but no further interpretation is done.

Since these dependencies are associated to the link rule used to create the programs they should normally list files used by the link command. That is *.$(OBJEXT), *.a, or *.la files. In rare cases you may need to add other kinds of files such as linker scripts, but listing a source file in _DEPENDENCIES is wrong. If some source file needs to be built before all the
components of a program are built, consider using the `BUILT_SOURCES` variable instead (see Section 9.4 [Sources], page 85).

If `prog_DEPENDENCIES` is not supplied, it is computed by Automake. The automatically-assigned value is the contents of `prog_LDADD`, with most configure substitutions, `-l`, `-L`, `-dlopen` and `-dlpreopen` options removed. The configure substitutions that are left in are only `${LIBOBJS}` and `${ALLOCA}`; these are left because it is known that they will not cause an invalid value for `prog_DEPENDENCIES` to be generated.

Section 8.1.3 [Conditional Sources], page 56, shows a situation where `DEPENDENCIES` may be used.

The `EXTRA_prog_DEPENDENCIES` may be useful for cases where you merely want to augment the `automake`-generated `prog_DEPENDENCIES` rather than replacing it.

We recommend that you avoid using `-l` options in `LDADD` or `prog_LDADD` when referring to libraries built by your package. Instead, write the file name of the library explicitly as in the above `cpio` example. Use `-l` only to list third-party libraries. If you follow this rule, the default value of `prog_DEPENDENCIES` will list all your local libraries and omit the other ones.

8.1.3 Conditional compilation of sources

You can’t put a configure substitution (e.g., ‘@FOO@’ or ‘$(FOO)’ where FOO is defined via `AC_SUBST`) into a `_SOURCES` variable. The reason for this is a bit hard to explain, but suffice to say that it simply won’t work. Automake will give an error if you try to do this.

Fortunately there are two other ways to achieve the same result. One is to use configure substitutions in `LDADD` variables, the other is to use an Automake conditional.

Conditional Compilation using `LDADD` Substitutions

Automake must know all the source files that could possibly go into a program, even if not all the files are built in every circumstance. Any files that are only conditionally built should be listed in the appropriate `EXTRA_` variable. For instance, if `hello-linux.c` or `hello-generic.c` were conditionally included in `hello`, the `Makefile.am` would contain:

```makefile
bin_PROGRAMS = hello
hello_SOURCES = hello-common.c
EXTRA_hello_SOURCES = hello-linux.c hello-generic.c
hello_LDADD = $(HELLO_SYSTEM)
hello_DEPENDENCIES = $(HELLO_SYSTEM)
```

You can then setup the ‘$(HELLO_SYSTEM)’ substitution from `configure.ac`:

```makefile
... case $host in
  *linux*) HELLO_SYSTEM='hello-linux.$(OBJEXT)' ;;
  *) HELLO_SYSTEM='hello-generic.$(OBJEXT)' ;;
esac
AC_SUBST([HELLO_SYSTEM])
...```

In this case, the variable `HELLO_SYSTEM` should be replaced by either `hello-linux.o` or `hello-generic.o`, and added to both `hello_DEPENDENCIES` and `hello_LDADD` in order to be built and linked in.
Conditional Compilation using Automake Conditionals

An often simpler way to compile source files conditionally is to use Automake conditionals. For instance, you could use this `Makefile.am` construct to build the same `hello` example:

```plaintext
bin_PROGRAMS = hello
if LINUX
    hello_SOURCES = hello-linux.c hello-common.c
else
    hello_SOURCES = hello-generic.c hello-common.c
endif
```

In this case, `configure.ac` should setup the `LINUX` conditional using `AM_CONDITIONAL` (see Chapter 20 [Conditionals], page 114).

When using conditionals like this you don’t need to use the `EXTRA_` variable, because Automake will examine the contents of each variable to construct the complete list of source files.

If your program uses a lot of files, you will probably prefer a conditional ‘+=’.

```plaintext
bin_PROGRAMS = hello
hello_SOURCES = hello-common.c
if LINUX
    hello_SOURCES += hello-linux.c
else
    hello_SOURCES += hello-generic.c
endif
```

8.1.4 Conditional compilation of programs

Sometimes it is useful to determine the programs that are to be built at configure time. For instance, GNU `cpio` only builds `mt` and `rmt` under special circumstances. The means to achieve conditional compilation of programs are the same you can use to compile source files conditionally: substitutions or conditionals.

Conditional Programs using `configure` Substitutions

In this case, you must notify Automake of all the programs that can possibly be built, but at the same time cause the generated `Makefile.in` to use the programs specified by `configure`. This is done by having `configure` substitute values into each `_PROGRAMS` definition, while listing all optionally built programs in `EXTRA_PROGRAMS`.

```plaintext
bin_PROGRAMS = cpio pax $(MT)
libexec_PROGRAMS = $(RMT)
EXTRA_PROGRAMS = mt rmt
```

As explained in Section 8.20 [EXEEXT], page 82, Automake will rewrite `bin_PROGRAMS`, `libexec_PROGRAMS`, and `EXTRA_PROGRAMS`, appending ‘$(EXEEXT)’ to each binary. Obviously it cannot rewrite values obtained at run-time through `configure` substitutions, therefore you should take care of appending ‘$(EXEEXT)’ yourself, as in ‘AC_SUBST([MT], ['mt$(EXEEXT)'])’. 
Conditional Programs using Automake Conditionals

You can also use Automake conditionals (see Chapter 20 [Conditionals], page 114) to select programs to be built. In this case you don’t have to worry about ‘$(EXEEXT)’ or EXTRA_PROGRAMS.

```
bin_PROGRAMS = cpio pax
if WANT_MT
    bin_PROGRAMS += mt
endif
if WANT_RMT
    libexec_PROGRAMS = rmt
endif
```

8.2 Building a library

Building a library is much like building a program. In this case, the name of the primary is LIBRARIES. Libraries can be installed in libdir or pkglibdir.

See Section 8.3 [A Shared Library], page 59, for information on how to build shared libraries using libtool and the LTLIBRARIES primary.

Each _LIBRARIES variable is a list of the libraries to be built. For instance, to create a library named libcpio.a, but not install it, you would write:

```
noinst_LIBRARIES = libcpio.a
libcpio_a_SOURCES = ...
```

The sources that go into a library are determined exactly as they are for programs, via the _SOURCES variables. Note that the library name is canonicalized (see Section 3.5 [Canonicalization], page 22), so the _SOURCES variable corresponding to libcpio.a is ‘libcpio_a_SOURCES’, not ‘libcpio.a_SOURCES’.

Extra objects can be added to a library using the library_LIBADD variable. This should be used for objects determined by configure. Again from cpio:

```
libcpio_a_LIBADD = $(LIBOBJS) $(ALLOCA)
```

In addition, sources for extra objects that will not exist until configure-time must be added to the BUILTIN_SOURCES variable (see Section 9.4 [Sources], page 85).

Building a static library is done by compiling all object files, then by invoking ‘$(AR) $(ARFLAGS)’ followed by the name of the library and the list of objects, and finally by calling ‘$(RANLIB)’ on that library. You should call AC_PROG_RANLIB from your configure.ac to define RANLIB (Automake will complain otherwise). You should also call AM_PROG_AR to define AR, in order to support unusual archivers such as Microsoft lib. ARFLAGS will default to cru; you can override this variable by setting it in your Makefile.am or by AC_SUBSTing it from your configure.ac. You can override the AR variable by defining a per-library maude_AR variable (see Section 8.4 [Program and Library Variables], page 65).

Be careful when selecting library components conditionally. Because building an empty library is not portable, you should ensure that any library always contains at least one object.

To use a static library when building a program, add it to LDADD for this program. In the following example, the program cpio is statically linked with the library libcpio.a.

```
noinst_LIBRARIES = libcpio.a
```
8.3 Building a Shared Library

Building shared libraries portably is a relatively complex matter. For this reason, GNU Libtool (see Section “Introduction” in The Libtool Manual) was created to help build shared libraries in a platform-independent way.

8.3.1 The Libtool Concept

Libtool abstracts shared and static libraries into a unified concept henceforth called libtool libraries. Libtool libraries are files using the .la suffix, and can designate a static library, a shared library, or maybe both. Their exact nature cannot be determined until ./configure is run: not all platforms support all kinds of libraries, and users can explicitly select which libraries should be built. (However the package’s maintainers can tune the default, see Section “The AC_PROG_LIBTOOL macro” in The Libtool Manual.)

Because object files for shared and static libraries must be compiled differently, libtool is also used during compilation. Object files built by libtool are called libtool objects: these are files using the .lo suffix. Libtool libraries are built from these libtool objects.

You should not assume anything about the structure of .la or .lo files and how libtool constructs them: this is libtool’s concern, and the last thing one wants is to learn about libtool’s guts. However the existence of these files matters, because they are used as targets and dependencies in Makefiles rules when building libtool libraries. There are situations where you may have to refer to these, for instance when expressing dependencies for building source files conditionally (see Section 8.3.4 [Conditional Libtool Sources], page 61).

People considering writing a plug-in system, with dynamically loaded modules, should look into libltdl: libtool’s dlopening library (see Section “Using libltdl” in The Libtool Manual). This offers a portable dlopening facility to load libtool libraries dynamically, and can also achieve static linking where unavoidable.

Before we discuss how to use libtool with Automake in details, it should be noted that the libtool manual also has a section about how to use Automake with libtool (see Section “Using Automake with Libtool” in The Libtool Manual).

8.3.2 Building Libtool Libraries

Automake uses libtool to build libraries declared with the LTLIBRARIES primary. Each _LTLIBRARIES variable is a list of libtool libraries to build. For instance, to create a libtool library named libgettext.la, and install it in libdir, write:

```
lib_LTLIBRARIES = libgettext.la
libgettext.la_SOURCES = gettext.c gettext.h ...
```

Automake predefines the variable pkglibdir, so you can use pkglib_LTLIBRARIES to install libraries in `$@libdir@/@@PACKAGE@/`.

If gettext.h is a public header file that needs to be installed in order for people to use the library, it should be declared using a _HEADERS variable, not in libgettext.la_
SOURCES. Headers listed in the latter should be internal headers that are not part of the public interface.

lib_LTLIBRARIES = libgettext.la
libgettext_la_SOURCES = gettext.c ...
include_HEADERS = gettext.h ...

A package can build and install such a library along with other programs that use it. This dependency should be specified using LDADD. The following example builds a program named hello that is linked with libgettext.la.

lib_LTLIBRARIES = libgettext.la
libgettext_la_SOURCES = gettext.c ...

bin_PROGRAMS = hello
hello_SOURCES = hello.c ...
hello_LDADD = libgettext.la

Whether hello is statically or dynamically linked with libgettext.la is not yet known: this will depend on the configuration of libtool and the capabilities of the host.

8.3.3 Building Libtool Libraries Conditionally

Like conditional programs (see Section 8.1.4 [Conditional Programs], page 57), there are two main ways to build conditional libraries: using Automake conditionals or using Autoconf AC_SUBSTitutions.

The important implementation detail you have to be aware of is that the place where a library will be installed matters to libtool: it needs to be indicated at link-time using the -rpath option.

For libraries whose destination directory is known when Automake runs, Automake will automatically supply the appropriate -rpath option to libtool. This is the case for libraries listed explicitly in some installable _LTLIBRARIES variables such as lib_LTLIBRARIES.

However, for libraries determined at configure time (and thus mentioned in EXTRA_LTLIBRARIES), Automake does not know the final installation directory. For such libraries you must add the -rpath option to the appropriate _LDFLAGS variable by hand.

The examples below illustrate the differences between these two methods.

Here is an example where WANTEDLIBS is an AC_SUBSTed variable set at ./configure-time to either libfoo.la, libbar.la, both, or none. Although ‘$(WANTEDLIBS)’ appears in the lib_LTLIBRARIES, Automake cannot guess it relates to libfoo.la or libbar.la at the time it creates the link rule for these two libraries. Therefore the -rpath argument must be explicitly supplied.

EXTRA_LTLIBRARIES = libfoo.la libbar.la
lib_LTLIBRARIES = $(WANTEDLIBS)
libfoo_la_SOURCES = foo.c ...
libfoo_la_LDFLAGS = -rpath ’$(libdir)’
libbar_la_SOURCES = bar.c ...
libbar_la_LDFLAGS = -rpath ’$(libdir)’

Here is how the same Makefile.am would look using Automake conditionals named WANT_LIBFOO and WANT_LIBBAR. Now Automake is able to compute the -rpath setting itself, because it’s clear that both libraries will end up in ‘$(libdir)’ if they are installed.
lib_LTLIBRARIES =
if WANT_LIBFOO
    lib_LTLIBRARIES += libfoo.la
endif
if WANT_LIBBAR
    lib_LTLIBRARIES += libbar.la
endif
libfoo_la_SOURCES = foo.c ...
libbar_la_SOURCES = bar.c ...

8.3.4 Libtool Libraries with Conditional Sources

Conditional compilation of sources in a library can be achieved in the same way as con-
titional compilation of sources in a program (see Section 8.1.3 [Conditional Sources], page 56). The only difference is that _LIBADD should be used instead of _LDADD and that it should mention libtool objects (.lo files).

So, to mimic the hello example from Section 8.1.3 [Conditional Sources], page 56, we could build a libhello.la library using either hello-linux.c or hello-generic.c with the following Makefile.am.

    lib_LTLIBRARIES = libhello.la
    libhello_la_SOURCES = hello-common.c
    EXTRA_libhello_la_SOURCES = hello-linux.c hello-generic.c
    libhello_la_LIBADD = $(HELLO_SYSTEM)
    libhello_la_DEPENDENCIES = $(HELLO_SYSTEM)

And make sure configure defines HELLO_SYSTEM as either hello-linux.lo or hello-
generic.lo.

Or we could simply use an Automake conditional as follows.

    lib_LTLIBRARIES = libhello.la
    libhello_la_SOURCES = hello-common.c
    if LINUX
        libhello_la_SOURCES += hello-linux.c
    else
        libhello_la_SOURCES += hello-generic.c
    endif

8.3.5 Libtool Convenience Libraries

Sometimes you want to build libtool libraries that should not be installed. These are called libtool convenience libraries and are typically used to encapsulate many sublibraries, later gathered into one big installed library.

Libtool convenience libraries are declared by directory-less variables such as noinst_ LTLIBRARIES, check_LTLIBRARIES, or even EXTRA_LTLIBRARIES. Unlike installed libtool libraries they do not need an -rpath flag at link time (actually this is the only difference).

Convenience libraries listed in noinst_LTLIBRARIES are always built. Those listed in check_LTLIBRARIES are built only upon `make check`. Finally, libraries listed in EXTRA_LTLIBRARIES are never built explicitly: Automake outputs rules to build them, but if the
library does not appear as a Makefile dependency anywhere it won’t be built (this is why `EXTRA_LTLIBRARIES` is used for conditional compilation).

Here is a sample setup merging `libtool` convenience libraries from subdirectories into one main `libtop.la` library.

```bash
# -- Top-level Makefile.am --
SUBDIRS = sub1 sub2 ...
lib_LTLIBRARIES = libtop.la
libtop_la_SOURCES =
    sub1/libsub1.la \
    sub2/libsub2.la \
...

# -- sub1/Makefile.am --
noinst_LTLIBRARIES = libsub1.la
libsub1_la_SOURCES = ...

# -- sub2/Makefile.am --
# showing nested convenience libraries
SUBDIRS = sub2.1 sub2.2 ...
noinst_LTLIBRARIES = libsub2.la
libsub2_la_SOURCES =
    sub21/libsub21.la \
    sub22/libsub22.la \
...
```

When using such setup, beware that `automake` will assume `libtop.la` is to be linked with the C linker. This is because `libtop_la_SOURCES` is empty, so `automake` picks C as default language. If `libtop_la_SOURCES` was not empty, `automake` would select the linker as explained in Section 8.13.3.1 [How the Linker is Chosen], page 78.

If one of the sublibraries contains non-C source, it is important that the appropriate linker be chosen. One way to achieve this is to pretend that there is such a non-C file among the sources of the library, thus forcing `automake` to select the appropriate linker. Here is the top-level `Makefile` of our example updated to force C++ linking.

```bash
SUBDIRS = sub1 sub2 ...
lib_LTLIBRARIES = libtop.la
libtop_la_SOURCES =
    # Dummy C++ source to cause C++ linking.
    nodist_EXTRA_libtop_la_SOURCES = dummy.cxx
    libtop_la_LIBADD = \
    sub1/libsub1.la \
    sub2/libsub2.la \
...
```

`'EXTRA_*_SOURCES'` variables are used to keep track of source files that might be compiled (this is mostly useful when doing conditional compilation using `AC_SUBST`, see Section 8.3.4
[Conditional Libtool Sources], page 61), and the nodist_ prefix means the listed sources are not to be distributed (see Section 8.4 [Program and Library Variables], page 65). In effect the file dummy.cxx does not need to exist in the source tree. Of course if you have some real source file to list in libtop_la_SOURCES there is no point in cheating with nodist_EXTRA_ libtop_la_SOURCES.

8.3.6 Libtool Modules
These are libtool libraries meant to be dlopened. They are indicated to libtool by passing -module at link-time.

pkglib_LTLIBRARIES = mymodule.la
mymodule_la_SOURCES = doit.c
mymodule_la_LDFLAGS = -module

Ordinarily, Automake requires that a library's name start with lib. However, when building a dynamically loadable module you might wish to use a "nonstandard" name. Automake will not complain about such nonstandard names if it knows the library being built is a libtool module, i.e., if -module explicitly appears in the library's _LDFLAGS variable (or in the common AM_LDFLAGS variable when no per-library _LDFLAGS variable is defined).

As always, AC_SUBST variables are black boxes to Automake since their values are not yet known when automake is run. Therefore if -module is set via such a variable, Automake cannot notice it and will proceed as if the library was an ordinary libtool library, with strict naming.

If mymodule_la_SOURCES is not specified, then it defaults to the single file mymodule.c (see Section 8.5 [Default SOURCES], page 69).

8.3.7 _LIBADD, _LDFLAGS, and _LIBTOOLFLAGS
As shown in previous sections, the 'library_LIBADD' variable should be used to list extra libtool objects (.lo files) or libtool libraries (.la) to add to library.

The 'library_LDFLAGS' variable is the place to list additional libtool linking flags, such as -version-info, -static, and a lot more. See Section “Link mode” in The Libtool Manual.

The libtool command has two kinds of options: mode-specific options and generic options. Mode-specific options such as the aforementioned linking flags should be lumped with the other flags passed to the tool invoked by libtool (hence the use of 'library_LDFLAGS' for libtool linking flags). Generic options include --tag=tag and --silent (see Section “Invoking libtool” in The Libtool Manual for more options) should appear before the mode selection on the command line; in Makefile.am's they should be listed in the 'library_LIBTOOLFLAGS' variable.

If 'library_LIBTOOLFLAGS' is not defined, then the variable AM_LIBTOOLFLAGS is used instead.

These flags are passed to libtool after the --tag=tag option computed by Automake (if any), so 'library_LIBTOOLFLAGS' (or AM_LIBTOOLFLAGS) is a good place to override or supplement the --tag=tag setting.

The libtool rules also use a LIBTOOLFLAGS variable that should not be set in Makefile.am: this is a user variable (see Section 28.6 [Flag Variables Ordering], page 134. It allows users to run 'make LIBTOOLFLAGS=--silent', for instance. Note that the
verbosity of libtool can also be influenced with the Automake silent-rules option (see Chapter 17 [Options], page 107).

### 8.3.8 LTLIBOBS and LTALLOCA

Where an ordinary library might include ‘$(LIBOBS)’ or ‘$(ALLOCA)’ (see Section 8.6 [LIBOBS], page 69), a libtool library must use ‘$(LTLIBOBS)’ or ‘$(LTALLOCA)’. This is required because the object files that libtool operates on do not necessarily end in .o.

Nowadays, the computation of LTLIBOBS from LIBOBS is performed automatically by Autoconf (see Section “AC_LIBOBS vs. LIBOBS” in The Autoconf Manual).

### 8.3.9 Common Issues Related to Libtool’s Use

#### 8.3.9.1 Error: ‘required file ‘./ltmain.sh’ not found’

Libtool comes with a tool called libtoolize that will install libtool’s supporting files into a package. Running this command will install ltmain.sh. You should execute it before aclocal and automake.

People upgrading old packages to newer autotools are likely to face this issue because older Automake versions used to call libtoolize. Therefore old build scripts do not call libtoolize.

Since Automake 1.6, it has been decided that running libtoolize was none of Automake’s business. Instead, that functionality has been moved into the autoreconf command (see Section “Using autoreconf” in The Autoconf Manual). If you do not want to remember what to run and when, just learn the autoreconf command. Hopefully, replacing existing bootstrap.sh or autogen.sh scripts by a call to autoreconf should also free you from any similar incompatible change in the future.

#### 8.3.9.2 Objects ‘created with both libtool and without’

Sometimes, the same source file is used both to build a libtool library and to build another non-libtool target (be it a program or another library).

Let’s consider the following Makefile.am.

```makefile
bin_PROGRAMS = prog
prog_SOURCES = prog.c foo.c ...

lib_LTLIBRARIES = libfoo.la
libfoo_la_SOURCES = foo.c ...
```

(In this trivial case the issue could be avoided by linking libfoo.la with prog instead of listing foo.c in prog_SOURCES. But let’s assume we really want to keep prog and libfoo.la separate.)

Technically, it means that we should build foo.$(OBJEXT) for prog, and foo.lo for libfoo.la. The problem is that in the course of creating foo.lo, libtool may erase (or replace) foo.$(OBJEXT), and this cannot be avoided.

Therefore, when Automake detects this situation it will complain with a message such as

```
object ‘foo.$(OBJEXT)’ created both with libtool and without
```
A workaround for this issue is to ensure that these two objects get different basenames. As explained in Section 28.7 [Renamed Objects], page 137, this happens automatically when per-targets flags are used.

```
bin_PROGRAMS = prog
prog_SOURCES = prog.c foo.c ...
prog_CFLAGS = $(AM_CFLAGS)
```

```
lib_LTLIBRARIES = libfoo.la
libfoo_la_SOURCES = foo.c ...
```

Adding ‘`prog_CFLAGS = $(AM_CFLAGS)`’ is almost a no-op, because when the `prog_CFLAGS` is defined, it is used instead of `AM_CFLAGS`. However as a side effect it will cause `prog.c` and `foo.c` to be compiled as `prog-prog.$(OBJEXT)` and `prog-foo.$(OBJEXT)`, which solves the issue.

### 8.4 Program and Library Variables

Associated with each program is a collection of variables that can be used to modify how that program is built. There is a similar list of such variables for each library. The canonical name of the program (or library) is used as a base for naming these variables.

In the list below, we use the name “maude” to refer to the program or library. In your `Makefile.am` you would replace this with the canonical name of your program. This list also refers to “maude” as a program, but in general the same rules apply for both static and dynamic libraries; the documentation below notes situations where programs and libraries differ.

**maude_SOURCES**

This variable, if it exists, lists all the source files that are compiled to build the program. These files are added to the distribution by default. When building the program, Automake will cause each source file to be compiled to a single `.o` file (or `.lo` when using libtool). Normally these object files are named after the source file, but other factors can change this. If a file in the `_SOURCES` variable has an unrecognized extension, Automake will do one of two things with it. If a suffix rule exists for turning files with the unrecognized extension into `.o` files, then `automake` will treat this file as it will any other source file (see Section 8.17 [Support for Other Languages], page 80). Otherwise, the file will be ignored as though it were a header file.

The prefixes `dist_` and `nodist_` can be used to control whether files listed in a `_SOURCES` variable are distributed. `dist_` is redundant, as sources are distributed by default, but it can be specified for clarity if desired.

It is possible to have both `dist_` and `nodist_` variants of a given `_SOURCES` variable at once; this lets you easily distribute some files and not others, for instance:

```
    nodist_maude_SOURCES = nodist.c
    dist_maude_SOURCES = dist-me.c
```

By default the output file (on Unix systems, the `.o` file) will be put into the current build directory. However, if the option `subdir-objects` is in effect in the
current directory then the .o file will be put into the subdirectory named after the source file. For instance, with subdir-objects enabled, sub/dir/file.c will be compiled to sub/dir/file.o. Some people prefer this mode of operation. You can specify subdir-objects in AUTOMAKE_OPTIONS (see Chapter 17 [Options], page 107).

EXTRA_maude_SOURCES
Automake needs to know the list of files you intend to compile statically. For one thing, this is the only way Automake has of knowing what sort of language support a given Makefile.in requires. This means that, for example, you can’t put a configure substitution like ‘@my_sources@’ into a ‘_SOURCES’ variable. If you intend to conditionally compile source files and use configure to substitute the appropriate object names into, e.g., _LDADD (see below), then you should list the corresponding source files in the EXTRA_ variable.

This variable also supports dist_ and nodist_ prefixes. For instance, nodist_EXTRA_maude_SOURCES would list extra sources that may need to be built, but should not be distributed.

maude_AR
A static library is created by default by invoking ‘$(AR) $(ARFLAGS)’ followed by the name of the library and then the objects being put into the library. You can override this by setting the _AR variable. This is usually used with C++; some C++ compilers require a special invocation in order to instantiate all the templates that should go into a library. For instance, the SGI C++ compiler likes this variable set like so:

```
libmaude_a_AR = $(CXX) -ar -o
```

maude_LIBADD
Extra objects can be added to a library using the _LIBADD variable. For instance, this should be used for objects determined by configure (see Section 8.2 [A Library], page 58).

In the case of libtool libraries, maude_LIBADD can also refer to other libtool libraries.

maude_LDADD
Extra objects (*.$(OBJEXT)) and libraries (*.a, *.la) can be added to a program by listing them in the _LDADD variable. For instance, this should be used for objects determined by configure (see Section 8.1.2 [Linking], page 55).

_LDADD and _LIBADD are inappropriate for passing program-specific linker flags (except for -l, -L, -dlopen and -dlpreopen). Use the _LDFLAGS variable for this purpose.

For instance, if your configure.ac uses AC_PATH_XTRA, you could link your program against the X libraries like so:

```
maude_LDADD = $(X_PRE_LIBS) $(X_LIBS) $(X_EXTRA_LIBS)
```

We recommend that you use -l and -L only when referring to third-party libraries, and give the explicit file names of any library built by your package.

---

4 There are other, more obscure reasons for this limitation as well.
Doing so will ensure that `maude_DEPENDENCIES` (see below) is correctly defined by default.

**maude_LDFLAGS**

This variable is used to pass extra flags to the link step of a program or a shared library. It overrides the `AM_LDFLAGS` variable.

**maude_LIBTOOLFLAGS**

This variable is used to pass extra options to `libtool`. It overrides the `AM_LIBTOOLFLAGS` variable. These options are output before `libtool`'s `--mode=` option, so they should not be mode-specific options (those belong to the compiler or linker flags). See Section 8.3.7 [Libtool Flags], page 63.

**maude_DEPENDENCIES**

**EXTRA_maude_DEPENDENCIES**

It is also occasionally useful to have a target (program or library) depend on some other file that is not actually part of that target. This can be done using the `_DEPENDENCIES` variable. Each target depends on the contents of such a variable, but no further interpretation is done.

Since these dependencies are associated to the link rule used to create the programs they should normally list files used by the link command. That is `*.$(OBJEXT)`, `*.a`, or `*.la` files for programs; `*.lo` and `*.la` files for Libtool libraries; and `*.$(OBJEXT)` files for static libraries. In rare cases you may need to add other kinds of files such as linker scripts, but listing a source file in `_DEPENDENCIES` is wrong. If some source file needs to be built before all the components of a program are built, consider using the `BUILT_SOURCES` variable (see Section 9.4 [Sources], page 85).

If `_DEPENDENCIES` is not supplied, it is computed by Automake. The automatically-assigned value is the contents of `_LDADD` or `_LIBADD`, with most configure substitutions, `-l`, `-L`, `-dlopen` and `-dlpreopen` options removed. The configure substitutions that are left in are only `$(LIBOBJS)` and `$(ALLOCA)`; these are left because it is known that they will not cause an invalid value for `_DEPENDENCIES` to be generated.

_/DEPENDENCIES_ is more likely used to perform conditional compilation using an `AC_SUBST` variable that contains a list of objects. See Section 8.1.3 [Conditional Sources], page 56, and Section 8.3.4 [Conditional Libtool Sources], page 61.

The `EXTRA_*_DEPENDENCIES` variable may be useful for cases where you merely want to augment the automake-generated `_DEPENDENCIES` variable rather than replacing it.

**maude_LINK**

You can override the linker on a per-program basis. By default the linker is chosen according to the languages used by the program. For instance, a program that includes C++ source code would use the C++ compiler to link. The `_LINK` variable must hold the name of a command that can be passed all the `.o` file names and libraries to link against as arguments. Note that the name of the underlying program is not passed to `_LINK`; typically one uses `"$@"`:

```
maude_LINK = $(CCLD) -magic -o $@
```
If a _LINK variable is not supplied, it may still be generated and used by Automake due to the use of per-target link flags such as _CFLAGS, _LDFLAGS or _LIBTOOLFLAGS, in cases where they apply.

maude_CCASFLAGS
maude_CFLAGS
maude_CPPFLAGS
maude_CXXFLAGS
maude_FFLAGS
maude_GCJFLAGS
maude_LFLAGS
maude_OBJCFLAGS
maude_RFLAGS
maude_UPCFLAGS
maude_YFLAGS

Automake allows you to set compilation flags on a per-program (or per-library) basis. A single source file can be included in several programs, and it will potentially be compiled with different flags for each program. This works for any language directly supported by Automake. These per-target compilation flags are _CCASFLAGS, _CFLAGS, _CPPFLAGS, _CXXFLAGS, _FFLAGS, _GCJFLAGS, _LFLAGS, _OBJCFLAGS, _RFLAGS, _UPCFLAGS, and _YFLAGS.

When using a per-target compilation flag, Automake will choose a different name for the intermediate object files. Ordinarily a file like sample.c will be compiled to produce sample.o. However, if the program’s _CFLAGS variable is set, then the object file will be named, for instance, maude-sample.o. (See also Section 28.7 [Renamed Objects], page 137.) The use of per-target compilation flags with C sources requires that the macro AM_PROG_CC_C_O be called from configure.ac.

In compilations with per-target flags, the ordinary ‘AM_’ form of the flags variable is not automatically included in the compilation (however, the user form of the variable is included). So for instance, if you want the hypothetical maude compilations to also use the value of AM_CFLAGS, you would need to write:

```
maude_CFLAGS = ... your flags ... $(AM_CFLAGS)
```

See Section 28.6 [Flag Variables Ordering], page 134, for more discussion about the interaction between user variables, ‘AM_’ shadow variables, and per-target variables.

maude_SHORTNAME

On some platforms the allowable file names are very short. In order to support these systems and per-target compilation flags at the same time, Automake allows you to set a “short name” that will influence how intermediate object files are named. For instance, in the following example,

```
bin_PROGRAMS = maude
maude_CPPFLAGS = -DSOMEFLAG
maude_SHORTNAME = m
maude_SOURCES = sample.c ...
```

the object file would be named m-sample.o rather than maude-sample.o.
This facility is rarely needed in practice, and we recommend avoiding it until you find it is required.

8.5 Default _SOURCES

_SOURCES variables are used to specify source files of programs (see Section 8.1 [A Program], page 54), libraries (see Section 8.2 [A Library], page 58), and Libtool libraries (see Section 8.3 [A Shared Library], page 59).

When no such variable is specified for a target, Automake will define one itself. The default is to compile a single C file whose base name is the name of the target itself, with any extension replaced by `AM_DEFAULT_SOURCE_EXT`, which defaults to `.c`.

For example if you have the following somewhere in your Makefile.am with no corresponding libfoo_a_SOURCES:

```
lib_LIBRARIES = libfoo.a sub/libc++.a
```

`libfoo.a` will be built using a default source file named `libfoo.c`, and `sub/libc++.a` will be built from `sub/libc++.c`. (In older versions `sub/libc++.a` would be built from `sub_libc__.a.c`, i.e., the default source was the canonized name of the target, with `.c` appended. We believe the new behavior is more sensible, but for backward compatibility Automake will use the old name if a file or a rule with that name exists and `AM_DEFAULT_SOURCE_EXT` is not used.)

Default sources are mainly useful in test suites, when building many test programs each from a single source. For instance, in

```
check_PROGRAMS = test1 test2 test3
AM_DEFAULT_SOURCE_EXT = .cpp
```

test1, test2, and test3 will be built from `test1.cpp`, `test2.cpp`, and `test3.cpp`. Without the last line, they will be built from `test1.c`, `test2.c`, and `test3.c`.

Another case where this is convenient is building many Libtool modules (`module_n.la`), each defined in its own file (`module_n.c`).

```
AM_LDFLAGS = -module
lib_LTLIBRARIES = module1.la module2.la module3.la
```

Finally, there is one situation where this default source computation needs to be avoided: when a target should not be built from sources. We already saw such an example in Section 4.2 [true], page 26; this happens when all the constituents of a target have already been compiled and just need to be combined using a _LDADD variable. Then it is necessary to define an empty _SOURCES variable, so that Automake does not compute a default.

```
bin_PROGRAMS = target
```

```
target_SOURCES =
target_LDADD = libmain.a libmisc.a
```

8.6 Special handling for LIBOBS and ALLOCA

The `$(LIBOBS)` and `$(ALLOCA)` variables list object files that should be compiled into the project to provide an implementation for functions that are missing or broken on the host system. They are substituted by `configure`. 
These variables are defined by Autoconf macros such as `AC_LIBOBJ`, `AC_REPLACE_FUNCS` (see Section “Generic Function Checks” in The Autoconf Manual), or `AC_FUNC_ALLOCA` (see Section “Particular Function Checks” in The Autoconf Manual). Many other Autoconf macros call `AC_LIBOBJ` or `AC_REPLACE_FUNCS` to populate `$LIBOBJS`.

Using these variables is very similar to doing conditional compilation using `AC_SUBST` variables, as described in Section 8.1.3 [Conditional Sources], page 56. That is, when building a program, `$LIBOBJS` and `$ALLOCA` should be added to the associated `*LDADD` variable, or to the `*_LIBADD` variable when building a library. However there is no need to list the corresponding sources in `EXTRA_*_SOURCES` nor to define `*_DEPENDENCIES`. Automake automatically adds `$LIBOBJS` and `$ALLOCA` to the dependencies, and it will discover the list of corresponding source files automatically (by tracing the invocations of the `AC_LIBSOURCE` Autoconf macros). If you have already defined `*_DEPENDENCIES` explicitly for an unrelated reason, then you either need to add these variables manually, or use `EXTRA_*_DEPENDENCIES` instead of `*_DEPENDENCIES`.

These variables are usually used to build a portability library that is linked with all the programs of the project. We now review a sample setup. First, `configure.ac` contains some checks that affect either `LIBOBJS` or `ALLOCA`.

```bash
# configure.ac
...
AC_CONFIG_LIBOBJ_DIR([lib])
...
AC_FUNC_MALLOC dnl May add malloc.$(OBJEXT) to LIBOBJS
AC_FUNC_MEMCMP dnl May add memcmp.$(OBJEXT) to LIBOBJS
AC_REPLACE_FUNCS([strdup]) dnl May add strdup.$(OBJEXT) to LIBOBJS
AC_FUNC_ALLOCA dnl May add alloca.$(OBJEXT) to ALLOCA
...
AC_CONFIG_FILES([
  lib/Makefile
  src/Makefile
])
AC_OUTPUT
```

The `AC_CONFIG_LIBOBJ_DIR` tells Autoconf that the source files of these object files are to be found in the `lib/` directory. Automake can also use this information, otherwise it expects the source files are to be in the directory where the `$LIBOBJS` and `$ALLOCA` variables are used.

The `lib/` directory should therefore contain `malloc.c`, `memcmp.c`, `strdup.c`, `alloca.c`. Here is its `Makefile.am`:

```bash
# lib/Makefile.am

noinst_LIBRARIES = libcompat.a
libcompat.a_SOURCES =
libcompat.a_LIBADD = $(LIBOBJS) $(ALLOCA)
```

The library can have any name, of course, and anyway it is not going to be installed: it just holds the replacement versions of the missing or broken functions so we can later link
them in. Many projects also include extra functions, specific to the project, in that library: they are simply added on the _SOURCES line.

There is a small trap here, though: ‘$(LIBOBJS)’ and ‘$(ALLOCA)’ might be empty, and building an empty library is not portable. You should ensure that there is always something to put in libcompat.a. Most projects will also add some utility functions in that directory, and list them in libcompat_a_SOURCES, so in practice libcompat.a cannot be empty.

Finally here is how this library could be used from the src/ directory.

```
# src/Makefile.am

# Link all programs in this directory with libcompat.a
LDADD = ../lib/libcompat.a
bin_PROGRAMS = tool1 tool2 ...
tool1_SOURCES = ...
tool2_SOURCES = ...
```

When option subdir-objects is not used, as in the above example, the variables ‘$(LIBOBJS)’ or ‘$(ALLOCA)’ can only be used in the directory where their sources lie. E.g., here it would be wrong to use ‘$(LIBOBJS)’ or ‘$(ALLOCA)’ in src/Makefile.am. However if both subdir-objects and AC_CONFIG_LIBOBJ_DIR are used, it is OK to use these variables in other directories. For instance src/Makefile.am could be changed as follows.

```
# src/Makefile.am

AUTOMAKE_OPTIONS = subdir-objects
LDADD = $(LIBOBJS) $(ALLOCA)

bin_PROGRAMS = tool1 tool2 ...
tool1_SOURCES = ...
tool2_SOURCES = ...
```

Because ‘$(LIBOBJS)’ and ‘$(ALLOCA)’ contain object file names that end with ‘.$(OBJEXT)’, they are not suitable for Libtool libraries (where the expected object extension is .lo): LTLIBOBJS and LTALLOCA should be used instead.

LTLIBOBJS is defined automatically by Autoconf and should not be defined by hand (as in the past), however at the time of writing LTALLOCA still needs to be defined from ALLOCA manually. See Section “AC_LIBOBJ vs. LIBOBJS” in The Autoconf Manual.

### 8.7 Variables used when building a program

Occasionally it is useful to know which Makefile variables Automake uses for compilations, and in which order (see Section 28.6 [Flag Variables Ordering], page 134); for instance, you might need to do your own compilation in some special cases.

Some variables are inherited from Autoconf; these are CC, CFLAGS, CPPFLAGS, DEFS, LDFLAGS, and LIBS.

There are some additional variables that Automake defines on its own:
**AM_CPPFLAGS**

The contents of this variable are passed to every compilation that invokes the C preprocessor; it is a list of arguments to the preprocessor. For instance, \texttt{-I} and \texttt{-D} options should be listed here.

Automake already provides some \texttt{-I} options automatically, in a separate variable that is also passed to every compilation that invokes the C preprocessor. In particular it generates \texttt{-I.}, \texttt{-I$(srcdir)}', and a \texttt{-I} pointing to the directory holding \texttt{config.h} (if you’ve used \texttt{AC_CONFIG_HEADERS} or \texttt{AM_CONFIG_HEADER}). You can disable the default \texttt{-I} options using the \texttt{nostdinc} option.

When a file to be included is generated during the build and not part of a distribution tarball, its location is under \texttt{$(builddir)$}, not under \texttt{$(srcdir)$}. This matters especially for packages that use header files placed in sub-directories and want to allow builds outside the source tree (see Section 2.2.6 \[VPATH Builds\], page 6). In that case we recommend to use a pair of \texttt{-I} options, such as, e.g., \texttt{-Isome/subdir -I$(srcdir)/some/subdir'} or \texttt{-I$(top_builddir)/some/subdir -I$(top_srcdir)/some/subdir’}. Note that the reference to the build tree should come before the reference to the source tree, so that accidentally leftover generated files in the source directory are ignored.

\texttt{AM_CPPFLAGS} is ignored in preference to a per-executable (or per-library) \texttt{_CPPFLAGS} variable if it is defined.

**INCLUDES**

This does the same job as \texttt{AM_CPPFLAGS} (or any per-target \texttt{_CPPFLAGS} variable if it is used). It is an older name for the same functionality. This variable is deprecated; we suggest using \texttt{AM_CPPFLAGS} and per-target \texttt{_CPPFLAGS} instead.

**AM_CFLAGS**

This is the variable the \texttt{Makefile.am} author can use to pass in additional C compiler flags. It is more fully documented elsewhere. In some situations, this is not used, in preference to the per-executable (or per-library) \texttt{_CFLAGS}.

**COMPILE**

This is the command used to actually compile a C source file. The file name is appended to form the complete command line.

**AM_LDFLAGS**

This is the variable the \texttt{Makefile.am} author can use to pass in additional linker flags. In some situations, this is not used, in preference to the per-executable (or per-library) \texttt{_LDFLAGS}.

**LINK**

This is the command used to actually link a C program. It already includes \texttt{\textasciitilde o $@} and the usual variable references (for instance, \texttt{CFLAGS}); it takes as “arguments” the names of the object files and libraries to link in. This variable is not used when the linker is overridden with a per-target \texttt{_LINK} variable or per-target flags cause Automake to define such a \texttt{_LINK} variable.

### 8.8 Yacc and Lex support

Automake has somewhat idiosyncratic support for Yacc and Lex.
Automake assumes that the .c file generated by yacc (or lex) should be named using the basename of the input file. That is, for a yacc source file foo.y, Automake will cause the intermediate file to be named foo.c (as opposed to y.tab.c, which is more traditional).

The extension of a yacc source file is used to determine the extension of the resulting C or C++ file. Files with the extension .y will be turned into .c files; likewise, .yy will become .cc; .y++, .c++; .yx; .cxx; and .yp; .cpp.

Likewise, lex source files can be used to generate C or C++; the extensions .1, .11, .1++, .1xx, and .1pp are recognized.

You should never explicitly mention the intermediate (C or C++) file in any SOURCES variable; only list the source file.

The intermediate files generated by yacc (or lex) will be included in any distribution that is made. That way the user doesn’t need to have yacc or lex.

If a yacc source file is seen, then your configure.ac must define the variable YACC. This is most easily done by invoking the macro AC_PROG_YACC (see Section “Particular Program Checks” in The Autoconf Manual).

When yacc is invoked, it is passed AM_YFLAGS and YFLAGS. The latter is a user variable and the former is intended for the Makefile.am author.

AM_YFLAGS is usually used to pass the -d option to yacc. Automake knows what this means and will automatically adjust its rules to update and distribute the header file built by ‘yacc -d’. What Automake cannot guess, though, is where this header will be used: it is up to you to ensure the header gets built before it is first used. Typically this is necessary in order for dependency tracking to work when the header is included by another file. The common solution is listing the header file in BUILT_SOURCES (see Section 9.4 [Sources], page 85) as follows.

```
BUILT_SOURCES = parser.h
AM_YFLAGS = -d
bin_PROGRAMS = foo
foo_SOURCES = ... parser.y ...
```

If a lex source file is seen, then your configure.ac must define the variable LEX. You can use AC_PROG_LEX to do this (see Section “Particular Program Checks” in The Autoconf Manual), but using AM_PROG_LEX macro (see Section 6.4 [Macros], page 44) is recommended.

When lex is invoked, it is passed AM_LFLAGS and LFLAGS. The latter is a user variable and the former is intended for the Makefile.am author.

When AM_MAINTAINER_MODE (see Section 28.2 [maintainer-mode], page 130) is used, the rebuild rule for distributed Yacc and Lex sources are only used when maintainer-mode is enabled, or when the files have been erased.

When lex or yacc sources are used, automake -i automatically installs an auxiliary program called ylwrap in your package (see Section 3.7 [Auxiliary Programs], page 23). This program is used by the build rules to rename the output of these tools, and makes it possible to include multiple yacc (or lex) source files in a single directory. (This is necessary because yacc’s output file name is fixed, and a parallel make could conceivably invoke more than one instance of yacc simultaneously.)

---

5 Please note that automake recognizes -d in AM_YFLAGS only if it is not clustered with other options; for example, it won’t be recognized if AM_YFLAGS is -dt, but it will be if AM_YFLAGS is -d -t or -d -t.
For *yacc*, simply managing locking is insufficient. The output of *yacc* always uses the same symbol names internally, so it isn’t possible to link two *yacc* parsers into the same executable.

We recommend using the following renaming hack used in *gdb*:

```c
#define yymaxdepth c_maxdepth
#define yyparse c_parse
#define yylex c_lex
#define yyerror c_error
#define yyval c_lval
#define yychar c_char
#define yydebug c_debug
#define yypact c_pact
#define yyr1 c_r1
#define yyr2 c_r2
#define yydef c_def
#define yychk c_chk
#define yypgo c_pgo
#define yyact c_act
#define yyexca c_exca
#define yyerrflag c_errflag
#define yynerrs c_nerrs
#define yyys c_s
#define yy_yys c_yys
#define yyystate c_state
#define yytmp c_tmp
#define yyv c_v
#define yy_yyv c_yyv
#define yyval c_val
#define yyllloc c_lloc
#define yyreds c_reds
#define yytoks c_toks
#define yylhs c_yylhs
#define yylen c_yylen
#define yydefred c_yydefred
#define yydgoto c_yydgoto
#define yysindex c_yysindex
#define yyrindex c_yyrindex
#define yygindex c_yygindex
#define yytable c_yytable
#define yycheck c_yycheck
#define yyname c_yyname
#define yyrule c_yyrule
```
For each define, replace the ‘c_’ prefix with whatever you like. These defines work for bison, byacc, and traditional yaccs. If you find a parser generator that uses a symbol not covered here, please report the new name so it can be added to the list.

8.9 C++ Support

Automake includes full support for C++.

Any package including C++ code must define the output variable CXX in configure.ac; the simplest way to do this is to use the AC_PROG_CXX macro (see Section “Particular Program Checks” in The Autoconf Manual).

A few additional variables are defined when a C++ source file is seen:

- CXX: The name of the C++ compiler.
- CXXFLAGS: Any flags to pass to the C++ compiler.
- AM_CXXFLAGS: The maintainer’s variant of CXXFLAGS.
- CXXCOMPILE: The command used to actually compile a C++ source file. The file name is appended to form the complete command line.
- CXXLINK: The command used to actually link a C++ program.

8.10 Objective C Support

Automake includes some support for Objective C.

Any package including Objective C code must define the output variable OBJC in configure.ac; the simplest way to do this is to use the AC_PROG_OBJC macro (see Section “Particular Program Checks” in The Autoconf Manual).

A few additional variables are defined when an Objective C source file is seen:

- OBJC: The name of the Objective C compiler.
- OBJCFLAGS: Any flags to pass to the Objective C compiler.
- AM_OBJCFLAGS: The maintainer’s variant of OBJCFLAGS.
- OBJCCOMPILE: The command used to actually compile an Objective C source file. The file name is appended to form the complete command line.
- OBJCLINK: The command used to actually link an Objective C program.

8.11 Unified Parallel C Support

Automake includes some support for Unified Parallel C.

Any package including Unified Parallel C code must define the output variable UPC in configure.ac; the simplest way to do this is to use the AM_PROG_UPC macro (see Section 6.4.1 [Public Macros], page 44).
A few additional variables are defined when a Unified Parallel C source file is seen:

- **UPC**  The name of the Unified Parallel C compiler.
- **UPCFLAGS**  Any flags to pass to the Unified Parallel C compiler.
- **AM_UPCFLAGS**  The maintainer’s variant of **UPCFLAGS**.
- **UPCCOMPILE**  The command used to actually compile a Unified Parallel C source file. The file name is appended to form the complete command line.
- **UPCLINK**  The command used to actually link a Unified Parallel C program.

### 8.12 Assembly Support

Automake includes some support for assembly code. There are two forms of assembler files: normal (*.s) and preprocessed by **CPP** (*.S or *.sx).

The variable **CCAS** holds the name of the compiler used to build assembly code. This compiler must work a bit like a C compiler; in particular it must accept -c and -o. The values of **CCASFLAGS** and **AM_CCASFLAGS** (or its per-target definition) is passed to the compilation. For preprocessed files, **DEFS**, **DEFAULT_INCLUDES**, **INCLUDES**, **CPPFLAGS** and **AM_CPPFLAGS** are also used.

The autoconf macro **AM_PROG_AS** will define **CCAS** and **CCASFLAGS** for you (unless they are already set, it simply sets **CCAS** to the C compiler and **CCASFLAGS** to the C compiler flags), but you are free to define these variables by other means.

Only the suffixes .s, .S, and .sx are recognized by **automake** as being files containing assembly code.

### 8.13 Fortran 77 Support

Automake includes full support for Fortran 77.

Any package including Fortran 77 code must define the output variable **F77** in **configure.ac**; the simplest way to do this is to use the **AC_PROG_F77** macro (see Section “Particular Program Checks” in The Autoconf Manual).

A few additional variables are defined when a Fortran 77 source file is seen:

- **F77**  The name of the Fortran 77 compiler.
- **FFLAGS**  Any flags to pass to the Fortran 77 compiler.
- **AM_FFLAGS**  The maintainer’s variant of **FFLAGS**.
- **RFLAGS**  Any flags to pass to the Ratfor compiler.
- **AM_RFLAGS**  The maintainer’s variant of **RFLAGS**.
- **F77COMPILE**  The command used to actually compile a Fortran 77 source file. The file name is appended to form the complete command line.
FLINK The command used to actually link a pure Fortran 77 program or shared library.

Automake can handle preprocessing Fortran 77 and Ratfor source files in addition to compiling them. Automake also contains some support for creating programs and shared libraries that are a mixture of Fortran 77 and other languages (see Section 8.13.3 [Mixing Fortran 77 With C and C++], page 77).

These issues are covered in the following sections.

8.13.1 Preprocessing Fortran 77

N.f is made automatically from N.F or N.r. This rule runs just the preprocessor to convert a preprocessable Fortran 77 or Ratfor source file into a strict Fortran 77 source file. The precise command used is as follows:

```
.F $(F77) -F $(DEFS) $(INCLUDES) $(AM_CPPFLAGS) $(CPPFLAGS)
    $(AM_FFLAGS) $(FFLAGS)
.r $(F77) -F $(AM_FFLAGS) $(FFLAGS) $(AM_RFLAGS) $(RFLAGS)
```

8.13.2 Compiling Fortran 77 Files

N.o is made automatically from N.f, N.F or N.r by running the Fortran 77 compiler. The precise command used is as follows:

```
.f $(F77) -c $(AM_FFLAGS) $(FFLAGS)
.F $(F77) -c $(DEFS) $(INCLUDES) $(AM_CPPFLAGS) $(CPPFLAGS)
    $(AM_FFLAGS) $(FFLAGS)
.r $(F77) -c $(AM_FFLAGS) $(FFLAGS) $(AM_RFLAGS) $(RFLAGS)
```

8.13.3 Mixing Fortran 77 With C and C++

Automake currently provides limited support for creating programs and shared libraries that are a mixture of Fortran 77 and C and/or C++. However, there are many other issues related to mixing Fortran 77 with other languages that are not (currently) handled by Automake, but that are handled by other packages.

Automake can help in two ways:

1. Automatic selection of the linker depending on which combinations of source code.
2. Automatic selection of the appropriate linker flags (e.g., -L and -l) to pass to the automatically selected linker in order to link in the appropriate Fortran 77 intrinsic and run-time libraries.

These extra Fortran 77 linker flags are supplied in the output variable FLIBS by the AC_F77_LIBRARY_LDFLAGS Autoconf macro supplied with newer versions of Autoconf (Autoconf version 2.13 and later). See Section “Fortran Compiler Characteristics” in The Autoconf Manual.

---

6 Much, if not most, of the information in the following sections pertaining to preprocessing Fortran 77 programs was taken almost verbatim from Section “Catalogue of Rules” in The GNU Make Manual.

7 For example, the cfortran package (http://www-zeus.desy.de/~burow/cfortran/) addresses all of these inter-language issues, and runs under nearly all Fortran 77, C and C++ compilers on nearly all platforms. However, cfortran is not yet Free Software, but it will be in the next major release.
If Automake detects that a program or shared library (as mentioned in some _PROGRAMS or _LTLIBRARIES primary) contains source code that is a mixture of Fortran 77 and C and/or C++, then it requires that the macro AC_F77_LIBRARY_LDFLAGS be called in configure.ac, and that either $(FLIBS) appear in the appropriate _LDADD (for programs) or _LIBADD (for shared libraries) variables. It is the responsibility of the person writing the Makefile.am to make sure that ‘$(FLIBS)’ appears in the appropriate _LDADD or _LIBADD variable.

For example, consider the following Makefile.am:

```makefile
bin_PROGRAMS = foo
foo_SOURCES  = main.cc foo.f
foo_LDADD    = libfoo.la $(FLIBS)

pkglib_LTLIBRARIES = libfoo.la
libfoo_la_SOURCES  = bar.f baz.c zardoz.cc
libfoo_la_LIBADD   = $(FLIBS)
```

In this case, Automake will insist that AC_F77_LIBRARY_LDFLAGS is mentioned in configure.ac. Also, if ‘$(FLIBS)’ hadn’t been mentioned in foo_LDADD and libfoo_la_LIBADD, then Automake would have issued a warning.

### 8.13.3.1 How the Linker is Chosen

When a program or library mixes several languages, Automake choose the linker according to the following priorities. (The names in parentheses are the variables containing the link command.)

1. Native Java (GCJLINK)
2. C++ (CXXLINK)
3. Fortran 77 (F77LINK)
4. Fortran (FCLINK)
5. Objective C (OBJCLINK)
6. Unified Parallel C (UPCLINK)
7. C (LINK)

For example, if Fortran 77, C and C++ source code is compiled into a program, then the C++ linker will be used. In this case, if the C or Fortran 77 linkers required any special libraries that weren’t included by the C++ linker, then they must be manually added to an _LDADD or _LIBADD variable by the user writing the Makefile.am.

Automake only looks at the file names listed in _SOURCES variables to choose the linker, and defaults to the C linker. Sometimes this is inconvenient because you are linking against a library written in another language and would like to set the linker more appropriately. See Section 8.3.5 [Libtool Convenience Libraries], page 61, for a trick with nodist_EXTRA_..._SOURCES.

A per-target _LINK variable will override the above selection. Per-target link flags will cause Automake to write a per-target _LINK variable according to the language chosen as above.
8.14 Fortran 9x Support

Automake includes support for Fortran 9x.

Any package including Fortran 9x code must define the output variable FC in `configure.ac`; the simplest way to do this is to use the `AC_PROG_FC` macro (see Section “Particular Program Checks” in *The Autoconf Manual*).

A few additional variables are defined when a Fortran 9x source file is seen:

- **FC**: The name of the Fortran 9x compiler.
- **FCFLAGS**: Any flags to pass to the Fortran 9x compiler.
- **AM_FCFLAGS**: The maintainer’s variant of FCFLAGS.
- **FCCOMPILE**: The command used to actually compile a Fortran 9x source file. The file name is appended to form the complete command line.
- **FCLINK**: The command used to actually link a pure Fortran 9x program or shared library.

8.14.1 Compiling Fortran 9x Files

The `.o` file is made automatically from `.f90`, `.f95`, `.f03`, or `.f08` by running the Fortran 9x compiler. The precise command used is as follows:

- `.f90`:
  ```
  $(FC) $(AM_FCFLAGS) $(FCFLAGS) -c $(FCFLAGS_f90) $<
  ```
- `.f95`:
  ```
  $(FC) $(AM_FCFLAGS) $(FCFLAGS) -c $(FCFLAGS_f95) $<
  ```
- `.f03`:
  ```
  $(FC) $(AM_FCFLAGS) $(FCFLAGS) -c $(FCFLAGS_f03) $<
  ```
- `.f08`:
  ```
  $(FC) $(AM_FCFLAGS) $(FCFLAGS) -c $(FCFLAGS_f08) $<
  ```

8.15 Compiling Java sources using gcj

Automake includes support for natively compiled Java, using gcj, the Java front end to the GNU Compiler Collection (rudimentary support for compiling Java to bytecode using the javac compiler is also present, albeit deprecated; see Section 10.4 [Java], page 89).

Any package including Java code to be compiled must define the output variable GCJ in `configure.ac`; the variable GCJFLAGS must also be defined somehow (either in `configure.ac` or `Makefile.am`). The simplest way to do this is to use the `AM_PROG_GCJ` macro.

By default, programs including Java source files are linked with gcj.

As always, the contents of `AM_GCJFLAGS` are passed to every compilation invoking gcj (in its role as an ahead-of-time compiler, when invoking it to create `.class` files, `AM_JAVACFLAGS` is used instead). If it is necessary to pass options to gcj from `Makefile.am`, this variable, and not the user variable GCJFLAGS, should be used.

 gcj can be used to compile `.java`, `.class`, `.zip`, or `.jar` files.

When linking, gcj requires that the main class be specified using the `--main=` option. The easiest way to do this is to use the `_LDFLAGS` variable for the program.
8.16 Vala Support

Automake provides initial support for Vala (http://www.vala-project.org/). This requires valac version 0.7.0 or later, and currently requires the user to use GNU make.

```
foo_SOURCES = foo.vala bar.vala zardoc.c
```

Any .vala file listed in a _SOURCES variable will be compiled into C code by the Vala compiler. The generated .c files are distributed. The end user does not need to have a Vala compiler installed.

Automake ships with an Autoconf macro called AM_PROG_VALAC that will locate the Vala compiler and optionally check its version number.

```
AM_PROG_VALAC ([minimum-version])
```

Try to find a Vala compiler in PATH. If it is found, the variable VALAC is set. Optionally a minimum release number of the compiler can be requested:

```
AM_PROG_VALAC([0.7.0])
```

There are a few variables that are used when compiling Vala sources:

```
VALAC Path to the Vala compiler.
VALAFLAGS Additional arguments for the Vala compiler.
AM_VALAFLAGS The maintainer’s variant of VALAFLAGS.
```

lib_LTLIBRARIES = libfoo.la
libfoo_la_SOURCES = foo.vala

Note that currently, you cannot use per-target *_VALAFLAGS (see Section 28.7 [Renamed Objects], page 137) to produce different C files from one Vala source file.

8.17 Support for Other Languages

Automake currently only includes full support for C, C++ (see Section 8.9 [C++ Support], page 75), Objective C (see Section 8.10 [Objective C Support], page 75), Fortran 77 (see Section 8.13 [Fortran 77 Support], page 76), Fortran 9x (see Section 8.14 [Fortran 9x Support], page 79), and Java (see Section 8.15 [Java Support with gcj], page 79). There is only rudimentary support for other languages, support for which will be improved based on user demand.

Some limited support for adding your own languages is available via the suffix rule handling (see Section 18.2 [Suffixes], page 112).

8.18 Automatic de-ANSI-fication (deprecated, soon to be removed)

The features described in this section are deprecated; you must not use any of them in new code, and remove their use from older but still maintained code: they will be withdrawn in the next major Automake release.

When the C language was standardized in 1989, there was a long transition period where package developers needed to worry about porting to older systems that did not support
ANSI C by default. These older systems are no longer in practical use and are no longer supported by their original suppliers, so developers need not worry about this problem any more.

Automake allows you to write packages that are portable to K&R C by de-ANSI-fying each source file before the actual compilation takes place.

If the Makefile.am variable AUTOMAKE_OPTIONS (see Chapter 17 [Options], page 107) contains the option ansi2knr then code to handle de-ANSI-fication is inserted into the generated Makefile.in.

This causes each C source file in the directory to be treated as ANSI C. If an ANSI C compiler is available, it is used. If no ANSI C compiler is available, the ansi2knr program is used to convert the source files into K&R C, which is then compiled.

The ansi2knr program is simple-minded. It assumes the source code will be formatted in a particular way; see the ansi2knr man page for details.

Support for the obsolete de-ANSI-fication feature requires the source files ansi2knr.c and ansi2knr.1 to be in the same package as the ANSI C source; these files are distributed with Automake. Also, the package configure.ac must call the macro AM_C_PROTOTYPES (see Section 6.4 [Macros], page 44).

Automake also handles finding the ansi2knr support files in some other directory in the current package. This is done by prepending the relative path to the appropriate directory to the ansi2knr option. For instance, suppose the package has ANSI C code in the src and lib subdirectories. The files ansi2knr.c and ansi2knr.1 appear in lib. Then this could appear in src/Makefile.am:

```
AUTOMAKE_OPTIONS = ../lib/ansi2knr
```

If no directory prefix is given, the files are assumed to be in the current directory.

Note that automatic de-ANSI-fication will not work when the package is being built for a different host architecture. That is because automake currently has no way to build ansi2knr for the build machine.

Using LIBOBJS with source de-ANSI-fication used to require hand-crafted code in configure to append ‘$U’ to basenames in LIBOBJS. This is no longer true today. Starting with version 2.54, Autoconf takes care of rewriting LIBOBJS and LTLIBOBJS. (see Section “AC_LIBOBJ vs. LIBOBJS” in The Autoconf Manual)

### 8.19 Automatic dependency tracking

As a developer it is often painful to continually update the Makefile.am whenever the include-file dependencies change in a project. Automake supplies a way to automatically track dependency changes (see Section 2.2.12 [Dependency Tracking], page 11).

Automake always uses complete dependencies for a compilation, including system headers. Automake’s model is that dependency computation should be a side effect of the build. To this end, dependencies are computed by running all compilations through a special wrapper program called depcomp. depcomp understands how to coax many different C and C++ compilers into generating dependency information in the format it requires. ‘automake -a’ will install depcomp into your source tree for you. If depcomp can’t figure out how to properly invoke your compiler, dependency tracking will simply be disabled for your build.
Experience with earlier versions of Automake (see Section 29.2 [Dependency Tracking Evolution], page 158) taught us that it is not reliable to generate dependencies only on the maintainer’s system, as configurations vary too much. So instead Automake implements dependency tracking at build time.

Automatic dependency tracking can be suppressed by putting `no-dependencies` in the variable `AUTOMAKE_OPTIONS`, or passing `no-dependencies` as an argument to `AM_INIT_AUTOMAKE` (this should be the preferred way). Or, you can invoke `automake` with the `-i` option. Dependency tracking is enabled by default.

The person building your package also can choose to disable dependency tracking by configuring with `--disable-dependency-tracking`.

### 8.20 Support for executable extensions

On some platforms, such as Windows, executables are expected to have an extension such as `.exe`. On these platforms, some compilers (GCC among them) will automatically generate `foo.exe` when asked to generate `foo`.

Automake provides mostly-transparent support for this. Unfortunately `mostly` doesn’t yet mean `fully`. Until the English dictionary is revised, you will have to assist Automake if your package must support those platforms.

One thing you must be aware of is that, internally, Automake rewrites something like this:

```
bin_PROGRAMS = liver
```

to this:

```
bin_PROGRAMS = liver$(EXEEXT)
```

The targets Automake generates are likewise given the ‘$(EXEEXT)’ extension.

The variables `TESTS` and `XFAIL_TESTS` (see Section 15.1 [Simple Tests], page 102) are also rewritten if they contain filenames that have been declared as programs in the same `Makefile`. (This is mostly useful when some programs from `check_PROGRAMS` are listed in `TESTS`.)

However, Automake cannot apply this rewriting to `configure` substitutions. This means that if you are conditionally building a program using such a substitution, then your `configure.ac` must take care to add ‘$(EXEEXT)’ when constructing the output variable.

With Autoconf 2.13 and earlier, you must explicitly use `AC_EXEEXT` to get this support. With Autoconf 2.50, `AC_EXEEXT` is run automatically if you configure a compiler (say, through `AC_PROG_CC`).

Sometimes maintainers like to write an explicit link rule for their program. Without executable extension support, this is easy—you simply write a rule whose target is the name of the program. However, when executable extension support is enabled, you must instead add the ‘$(EXEEXT)’ suffix.

Unfortunately, due to the change in Autoconf 2.50, this means you must always add this extension. However, this is a problem for maintainers who know their package will never run on a platform that has executable extensions. For those maintainers, the `no-exeext` option (see Chapter 17 [Options], page 107) will disable this feature. This works in a fairly ugly way; if `no-exeext` is seen, then the presence of a rule for a target named `foo` in
Makefile.am will override an automake-generated rule for ‘foo$(EXEEXT)’. Without the no-exeext option, this use will give a diagnostic.

9 Other Derived Objects

Automake can handle derived objects that are not C programs. Sometimes the support for actually building such objects must be explicitly supplied, but Automake will still automatically handle installation and distribution.

9.1 Executable Scripts

It is possible to define and install programs that are scripts. Such programs are listed using the SCRIPTS primary name. When the script is distributed in its final, installable form, the Makefile usually looks as follows:

```
# Install my_script in $(bindir) and distribute it.
dist_bin_SCRIPTS = my_script
```

Scripts are not distributed by default; as we have just seen, those that should be distributed can be specified using a dist_ prefix as with other primaries.

Scripts can be installed in bindir, sbindir, libexecdir, pkglibexecdir, or pkgdatadir.

Scripts that need not be installed can be listed in noinst_SCRIPTS, and among them, those which are needed only by ‘make check’ should go in check_SCRIPTS.

When a script needs to be built, the Makefile.am should include the appropriate rules. For instance the automate program itself is a Perl script that is generated from automate.in. Here is how this is handled:

```
bin_SCRIPTS = automate
CLEANFILES = $(bin_SCRIPTS)
EXTRA_DIST = automate.in

do_subst = sed -e 's,[0]datadir[0],$(datadir),g' \
           -e 's,[0]PERL[0],$(PERL),g' \
           -e 's,[0]PACKAGE[0],$(PACKAGE),g' \
           -e 's,[0]VERSION[0],$(VERSION),g' \
        ...

automake: automate.in Makefile
        $(do_subst) < $(srcdir)/automate.in > automate
        chmod +x automate
```

Such scripts for which a build rule has been supplied need to be deleted explicitly using CLEANFILES (see Chapter 13 [Clean], page 97), and their sources have to be distributed, usually with EXTRA_DIST (see Section 14.1 [Basics of Distribution], page 98).

Another common way to build scripts is to process them from configure with AC_CONFIG_FILES. In this situation Automake knows which files should be cleaned and distributed, and what the rebuild rules should look like.
For instance if configure.ac contains

AC_CONFIG_FILES([src/my_script], [chmod +x src/my_script])

to build src/my_script from src/my_script.in, then a src/Makefile.am to install this
script in $(bindir) can be as simple as

bin_SCRIPTS = my_script
CLEANFILES = $(bin_SCRIPTS)

There is no need for EXTRA_DIST or any build rule: Automake infers them from AC_CONFIG_FILES (see Section 6.1 [Requirements], page 30). CLEANFILES is still useful, because by
default Automake will clean targets of AC_CONFIG_FILES in distclean, not clean.

Although this looks simpler, building scripts this way has one drawback: directory vari-
ables such as $(datadir) are not fully expanded and may refer to other directory variables.

9.2 Header files

Header files that must be installed are specified by the HEADERS family of variables. Headers
can be installed in includedir, oldincludedir, pkgincludedir or any other directory you
may have defined (see Section 3.3 [Uniform], page 20). For instance,

include_HEADERS = foo.h bar/bar.h

will install the two files as $(includedir)/foo.h and $(includedir)/bar.h.

The nobase_ prefix is also supported,

nobase_include_HEADERS = foo.h bar/bar.h

will install the two files as $(includedir)/foo.h and $(includedir)/bar/bar.h (see
Section 7.3 [Alternative], page 52).

Usually, only header files that accompany installed libraries need to be installed. Headers
used by programs or convenience libraries are not installed. The noinst_HEADERS variable
can be used for such headers. However when the header actually belongs to a single conve-
nience library or program, we recommend listing it in the program’s or library’s _SOURCES
variable (see Section 8.1.1 [Program Sources], page 54) instead of in noinst_HEADERS. This
is clearer for the Makefile.am reader. noinst_HEADERS would be the right variable to use
in a directory containing only headers and no associated library or program.

All header files must be listed somewhere; in a _SOURCES variable or in a _HEADERS
variable. Missing ones will not appear in the distribution.

For header files that are built and must not be distributed, use the nodist_ prefix as in
nodist_include_HEADERS or nodist_prog_SOURCES. If these generated headers are
needed during the build, you must also ensure they exist before they are used (see Section 9.4
[Sources], page 85).

9.3 Architecture-independent data files

Automake supports the installation of miscellaneous data files using the DATA family of
variables.

Such data can be installed in the directories datadir, sysconfdir, sharedstatedir,
localstatedir, or pkgdatadir.

By default, data files are not included in a distribution. Of course, you can use the
dist_ prefix to change this on a per-variable basis.
Here is how Automake declares its auxiliary data files:

\[\text{dist\_pkgdata\_DATA = clean-kr.am clean.am ...}\]

### 9.4 Built Sources

Because Automake’s automatic dependency tracking works as a side-effect of compilation (see Section 8.19 [Dependencies], page 81) there is a bootstrap issue: a target should not be compiled before its dependencies are made, but these dependencies are unknown until the target is first compiled.

Ordinarily this is not a problem, because dependencies are distributed sources: they preexist and do not need to be built. Suppose that foo.c includes foo.h. When it first compiles foo.o, make only knows that foo.o depends on foo.c. As a side-effect of this compilation depcomp records the foo.h dependency so that following invocations of make will honor it. In these conditions, it’s clear there is no problem: either foo.o doesn’t exist and has to be built (regardless of the dependencies), or accurate dependencies exist and they can be used to decide whether foo.o should be rebuilt.

It’s a different story if foo.h doesn’t exist by the first make run. For instance, there might be a rule to build foo.h. This time file.o’s build will fail because the compiler can’t find foo.h. make failed to trigger the rule to build foo.h first by lack of dependency information.

The `BUILT_SOURCES` variable is a workaround for this problem. A source file listed in `BUILT_SOURCES` is made on `make all` or `make check` (or even `make install`) before other targets are processed. However, such a source file is not compiled unless explicitly requested by mentioning it in some other `_SOURCES` variable.

So, to conclude our introductory example, we could use `BUILT_SOURCES = foo.h` to ensure foo.h gets built before any other target (including foo.o) during `make all` or `make check`.

`BUILT_SOURCES` is actually a bit of a misnomer, as any file which must be created early in the build process can be listed in this variable. Moreover, all built sources do not necessarily have to be listed in `BUILT_SOURCES`. For instance, a generated .c file doesn’t need to appear in `BUILT_SOURCES` (unless it is included by another source), because it’s a known dependency of the associated object.

It might be important to emphasize that `BUILT_SOURCES` is honored only by `make all`, `make check` and `make install`. This means you cannot build a specific target (e.g., `make foo`) in a clean tree if it depends on a built source. However it will succeed if you have run `make all` earlier, because accurate dependencies are already available.

The next section illustrates and discusses the handling of built sources on a toy example.

#### 9.4.1 Built Sources Example

Suppose that foo.c includes bindir.h, which is installation-dependent and not distributed: it needs to be built. Here bindir.h defines the preprocessor macro bindir to the value of the make variable bindir (inherited from configure).

We suggest several implementations below. It’s not meant to be an exhaustive listing of all ways to handle built sources, but it will give you a few ideas if you encounter this issue.
First Try

This first implementation will illustrate the bootstrap issue mentioned in the previous section (see Section 9.4 [Sources], page 85).

Here is a tentative `Makefile.am`.

```plaintext
# This won't work.
bin_PROGRAMS = foo
foo_SOURCES = foo.c
nodist_foo_SOURCES = bindir.h
CLEANFILES = bindir.h
bindir.h: Makefile
  echo '#define bindir "$(bindir)"' >$@

This setup doesn't work, because Automake doesn't know that `foo.c` includes `bindir.h`. Remember, automatic dependency tracking works as a side-effect of compilation, so the dependencies of `foo.o` will be known only after `foo.o` has been compiled (see Section 8.19 [Dependencies], page 81). The symptom is as follows.

```bash
% make
source='foo.c' object='foo.o' libtool=no \ 
   depfile='.deps/foo.Po' tmpdepfile='.deps/foo.TPo' \ 
   depmode=gcc /bin/sh ./depcomp 
   gcc -I. -I. -g -O2 -c 'test -f 'foo.c'' || echo './''foo.c
foo.c:2: bindir.h: No such file or directory
make: *** [foo.o] Error 1
```

In this example `bindir.h` is not distributed nor installed, and it is not even being built on-time. One may wonder if the `nodist_foo_SOURCES = bindir.h` line has any use at all. This line simply states that `bindir.h` is a source of `foo`, so for instance, it should be inspected while generating tags (see Section 18.1 [Tags], page 112). In other words, it does not help our present problem, and the build would fail identically without it.

Using `BUILT_SOURCES`

A solution is to require `bindir.h` to be built before anything else. This is what `BUILT_SOURCES` is meant for (see Section 9.4 [Sources], page 85).

```plaintext
bin_PROGRAMS = foo
foo_SOURCES = foo.c
nodist_foo_SOURCES = bindir.h
BUILT_SOURCES = bindir.h
CLEANFILES = bindir.h
bindir.h: Makefile
  echo '#define bindir "$(bindir)"' >$@
```

See how `bindir.h` gets built first:

```bash
% make
make all-am
make[1]: Entering directory '/home/adl/tmp' 
source='foo.c' object='foo.o' libtool=no \ 
   depfile='.deps/foo.Po' tmpdepfile='.deps/foo.TPo' \ 
```
Chapter 9: Other Derived Objects

```bash
depmode=gcc /bin/sh ./depcomp \
gcc -I. -I. -g -O2 -c 'test -f 'foo.c' || echo './''foo.c'
gcc -g -O2 -o foo foo.o
make[1]: Leaving directory '/home/adl/tmp'
```

However, as said earlier, BUILT_SOURCES applies only to the all, check, and install targets. It still fails if you try to run `make foo` explicitly:

```bash
% make clean
test -z "bindir.h" || rm -f bindir.h
test -z "foo" || rm -f foo
rm -f *.
% : > .deps/foo.Po # Suppress previously recorded dependencies
% make foo
source='foo.c' object='foo.o' libtool=no \n depfile='.deps/foo.Po' tmpdepfile='.deps/foo.TPo' \n depmode=gcc /bin/sh ./depcomp \
gcc -I. -I. -g -O2 -c 'test -f 'foo.c' || echo './''foo.c'
foo.c:2: bindir.h: No such file or directory
make: *** [foo.o] Error 1
```

### Recording Dependencies manually

Usually people are happy enough with BUILT_SOURCES because they never build targets such as `make foo` before `make all`, as in the previous example. However if this matters to you, you can avoid BUILT_SOURCES and record such dependencies explicitly in the `Makefile.am`.

```makefile
bin_PROGRAMS = foo
foo_SOURCES = foo.c
nodist_foo_SOURCES = bindir.h
foo.$(OBJEXT): bindir.h
CLEANFILES = bindir.h
bindir.h: Makefile
    echo '#define bindir "$(bindir)"' >$@
```

You don’t have to list all the dependencies of `foo.o` explicitly, only those that might need to be built. If a dependency already exists, it will not hinder the first compilation and will be recorded by the normal dependency tracking code. (Note that after this first compilation the dependency tracking code will also have recorded the dependency between `foo.o` and `bindir.h`; so our explicit dependency is really useful to the first build only.)

Adding explicit dependencies like this can be a bit dangerous if you are not careful enough. This is due to the way Automake tries not to overwrite your rules (it assumes you know better than it). `foo.$(OBJEXT): bindir.h` supersedes any rule Automake may want to output to build `foo.$(OBJEXT)`’. It happens to work in this case because Automake doesn’t have to output any `foo.$(OBJEXT):` target: it relies on a suffix rule instead (i.e., `.c.$(OBJEXT):`). Always check the generated `Makefile.in` if you do this.

### Build bindir.h from configure

It’s possible to define this preprocessor macro from `configure`, either in `config.h` (see Section “Defining Directories” in *The Autoconf Manual*), or by processing a `bindir.h.in` file using `AC_CONFIG_FILES` (see Section “Configuration Actions” in *The Autoconf Manual*).
At this point it should be clear that building *bindir.h* from *configure* works well for this example. *bindir.h* will exist before you build any target, hence will not cause any dependency issue.

The Makefile can be shrunk as follows. We do not even have to mention *bindir.h*.

```
bin_PROGRAMS = foo
foo_SOURCES = foo.c
```

However, it’s not always possible to build sources from *configure*, especially when these sources are generated by a tool that needs to be built first.

**Build *bindir.c*, not *bindir.h***.

Another attractive idea is to define *bindir* as a variable or function exported from *bindir.o*, and build *bindir.c* instead of *bindir.h*.

```
noinst_PROGRAMS = foo
foo_SOURCES = foo.c bindir.h
nodist_foo_SOURCES = bindir.c
CLEANFILES = bindir.c
bindir.c: Makefile
    echo 'const char bindir[] = "$(bindir)"; \n' >@
```

*bindir.h* contains just the variable’s declaration and doesn’t need to be built, so it won’t cause any trouble. *bindir.o* is always dependent on *bindir.c*, so *bindir.c* will get built first.

**Which is best?**

There is no panacea, of course. Each solution has its merits and drawbacks.

You cannot use BUILT_SOURCES if the ability to run ‘*make foo*’ on a clean tree is important to you.

You won’t add explicit dependencies if you are leery of overriding an Automake rule by mistake.

Building files from *configure* is not always possible, neither is converting *.h* files into *.c* files.

## 10 Other GNU Tools

Since Automake is primarily intended to generate *Makefile.in* for use in GNU programs, it tries hard to interoperate with other GNU tools.

### 10.1 Emacs Lisp

Automake provides some support for Emacs Lisp. The LISP primary is used to hold a list of *.el* files. Possible prefixes for this primary are lisp_ and noinst_. Note that if lisp_LISP is defined, then *configure.ac* must run AM_PATH_LISPDIR (see Section 6.4 [Macros], page 44).

Lisp sources are not distributed by default. You can prefix the LISP primary with dist_, as in dist_lisp_LISP or dist_noinst_LISP, to indicate that these files should be distributed.
Automake will byte-compile all Emacs Lisp source files using the Emacs found by \texttt{AM\_PATH\_LISPDIR}, if any was found.

Byte-compiled Emacs Lisp files are not portable among all versions of Emacs, so it makes sense to turn this off if you expect sites to have more than one version of Emacs installed. Furthermore, many packages don’t actually benefit from byte-compilation. Still, we recommend that you byte-compile your Emacs Lisp sources. It is probably better for sites with strange setups to cope for themselves than to make the installation less nice for everybody else.

There are two ways to avoid byte-compiling. Historically, we have recommended the following construct.

\begin{verbatim}
lisp\_LISP = file1.el file2.el
ELCFILES =
\end{verbatim}

\texttt{ELCFILES} is an internal Automake variable that normally lists all .elc files that must be byte-compiled. Automake defines \texttt{ELCFILES} automatically from \texttt{lisp\_LISP}. Emptying this variable explicitly prevents byte-compilation.

Since Automake 1.8, we now recommend using \texttt{lisp\_DATA} instead:

\begin{verbatim}
lisp\_DATA = file1.el file2.el
\end{verbatim}

Note that these two constructs are not equivalent. \texttt{\_LISP} will not install a file if Emacs is not installed, while \texttt{\_DATA} will always install its files.

\section*{10.2 Gettext}

If \texttt{AM\_GNU\_GETTEXT} is seen in \texttt{configure.ac}, then Automake turns on support for GNU gettext, a message catalog system for internationalization (see Section “Introduction” in GNU gettext utilities).

The \texttt{gettext} support in Automake requires the addition of one or two subdirectories to the package: \texttt{po} and possibly also \texttt{intl}. The latter is needed if \texttt{AM\_GNU\_GETTEXT} is not invoked with the `external' argument, or if \texttt{AM\_GNU\_GETTEXT\_INTL\_SUBDIR} is used. Automake ensures that these directories exist and are mentioned in \texttt{SUBDIRS}.

\section*{10.3 Libtool}

Automake provides support for GNU Libtool (see Section “Introduction” in The Libtool Manual) with the \texttt{LTLIBRARIES} primary. See Section 8.3 [A Shared Library], page 59.

\section*{10.4 Java bytecode compilation (deprecated)}

Automake provides some minimal support for Java bytecode compilation with the \texttt{JAVA} primary (in addition to the support for compiling Java to native machine code; see Section 8.15 [Java Support with gcj], page 79). Note however that the interface and most features described here are deprecated; the next automake release will strive to provide a better and cleaner interface, which however \textit{won’t be backward-compatible}; the present interface will probably be removed altogether in future automake releases (1.13 or later), so don’t use it in new code.

Any .java files listed in a \texttt{\_JAVA} variable will be compiled with \texttt{JAVAC} at build time. By default, .java files are not included in the distribution, you should use the \texttt{dist\_} prefix to distribute them.
Here is a typical setup for distributing .java files and installing the .class files resulting from their compilation.

```bash
ejavadir = $(datadir)/java
dist_java_JAVA = a.java b.java ...
```

Currently Automake enforces the restriction that only one _JAVA primary can be used in a given Makefile.am. The reason for this restriction is that, in general, it isn’t possible to know which .class files were generated from which .java files, so it would be impossible to know which files to install where. For instance, a .java file can define multiple classes; the resulting .class file names cannot be predicted without parsing the .java file.

There are a few variables that are used when compiling Java sources:

- **JAVAC** The name of the Java compiler. This defaults to ‘javac’.
- **JAVACFLAGS** The flags to pass to the compiler. This is considered to be a user variable (see Section 3.6 [User Variables], page 23).
- **AM_JAVACFLAGS** More flags to pass to the Java compiler. This, and not JAVACFLAGS, should be used when it is necessary to put Java compiler flags into Makefile.am.
- **JAVAROOT** The value of this variable is passed to the -d option to javac. It defaults to ‘$(top_builddir)’.
- **CLASSPATH_ENV** This variable is a shell expression that is used to set the CLASSPATH environment variable on the javac command line. (In the future we will probably handle class path setting differently.)

### 10.5 Python

Automake provides support for Python compilation with the PYTHON primary. A typical setup is to call AM_PATH_PYTHON in configure.ac and use a line like the following in Makefile.am:

```bash
python_PYTHON = tree.py leave.py
```

Any files listed in a _PYTHON variable will be byte-compiled with py-compile at install time. py-compile actually creates both standard (.pyc) and optimized (.pyo) byte-compiled versions of the source files. Note that because byte-compilation occurs at install time, any files listed in noinst_PYTHON will not be compiled. Python source files are included in the distribution by default, prepend nodist_ (as in nodist_python_PYTHON) to omit them.

Automake ships with an Autoconf macro called AM_PATH_PYTHON that will determine some Python-related directory variables (see below). If you have called AM_PATH_PYTHON from configure.ac, then you may use the variables python_PYTHON or pkgpython_PYTHON to list Python source files in your Makefile.am, depending on where you want your files installed (see the definitions of pythondir and pkgpythondir below).

```bash
AM_PATH_PYTHON ([version], [action-if-found], [action-if-not-found])
```
Search for a Python interpreter on the system. This macro takes three optional arguments. The first argument, if present, is the minimum version of Python required for this package: AM_PATH_PYTHON will skip any Python interpreter that is older than version. If an interpreter is found and satisfies version, then action-if-found is run. Otherwise, action-if-not-found is run.

If action-if-not-found is not specified, as in the following example, the default is to abort configure.

\texttt{AM_PATH_PYTHON([2.2])}

This is fine when Python is an absolute requirement for the package. If Python $\geq 2.5$ was only optional to the package, AM_PATH_PYTHON could be called as follows.

\texttt{AM_PATH_PYTHON([2.5], , [:])}

If the PYTHON variable is set when AM_PATH_PYTHON is called, then that will be the only Python interpreter that is tried.

AM_PATH_PYTHON creates the following output variables based on the Python installation found during configuration.

\textbf{PYTHON} The name of the Python executable, or ‘:’ if no suitable interpreter could be found.

Assuming action-if-not-found is used (otherwise ./configure will abort if Python is absent), the value of PYTHON can be used to setup a conditional in order to disable the relevant part of a build as follows.

\texttt{AM_PATH_PYTHON(, , [:])}

\texttt{AM_CONDITIONAL([HAVE_PYTHON], [test "$PYTHON" != :])}

\textbf{PYTHON_VERSION} The Python version number, in the form major.minor (e.g., ‘2.5’). This is currently the value of ‘\texttt{sys.version[:3]}’.

\textbf{PYTHON_PREFIX} The string ‘\texttt{$\{prefix\}$}’. This term may be used in future work that needs the contents of Python’s ‘\texttt{sys.prefix}’, but general consensus is to always use the value from configure.

\textbf{PYTHON_EXEC_PREFIX} The string ‘\texttt{$\{exec_prefix\}$}’. This term may be used in future work that needs the contents of Python’s ‘\texttt{sys.exec_prefix}’, but general consensus is to always use the value from configure.

\textbf{PYTHON_PLATFORM} The canonical name used by Python to describe the operating system, as given by ‘\texttt{sys.platform}’. This value is sometimes needed when building Python extensions.

\textbf{pythondir} The directory name for the \texttt{site-packages} subdirectory of the standard Python install tree.

\textbf{pkgpythondir} This is the directory under pythondir that is named after the package. That is, it is ‘\texttt{$(pythondir)/$(PACKAGE)$}’. It is provided as a convenience.
pyexecdir

This is the directory where Python extension modules (shared libraries) should be installed. An extension module written in C could be declared as follows to Automake:

```make
pyexec_LTLIBRARIES = quaternion.la
quaternion_la_SOURCES = quaternion.c support.c support.h
quaternion_la_LDFLAGS = -avoid-version -module
```

pkgpyexecdir

This is a convenience variable that is defined as `$(pyexecdir)/$(PACKAGE)`.

All these directory variables have values that start with either `{prefix}` or `{exec_prefix}` unexpanded. This works fine in Makefiles, but it makes these variables hard to use in configure. This is mandated by the GNU coding standards, so that the user can run `make prefix=/foo install`. The Autoconf manual has a section with more details on this topic (see Section “Installation Directory Variables” in The Autoconf Manual). See also Section 28.10 [Hard-Coded Install Paths], page 143.

11 Building documentation

Currently Automake provides support for Texinfo and man pages.

11.1 Texinfo

If the current directory contains Texinfo source, you must declare it with the TEXINFOS primary. Generally Texinfo files are converted into info, and thus the info_TEXINFOS variable is most commonly used here. Any Texinfo source file must end in the .texi, .txi, or .texinfo extension. We recommend .texi for new manuals.

Automake generates rules to build .info, .dvi, .ps, .pdf and .html files from your Texinfo sources. Following the GNU Coding Standards, only the .info files are built by `make all` and installed by `make install` (unless you use no-installinfo, see below). Furthermore, .info files are automatically distributed so that Texinfo is not a prerequisite for installing your package.

Other documentation formats can be built on request by `make dvi`, `make ps`, `make pdf` and `make html`, and they can be installed with `make install-dvi`, `make install-ps`, `make install-pdf` and `make install-html` explicitly. `make uninstall` will remove everything: the Texinfo documentation installed by default as well as all the above optional formats.

All these targets can be extended using `-local` rules (see Section 24.1 [Extending], page 121).

If the .texi file @includes version.texi, then that file will be automatically generated. The file version.texi defines four Texinfo flag you can reference using @value{EDITION}, @value{VERSION}, @value{UPDATED}, and @value{UPDATED-MONTH}.

EDITION
VERSION

Both of these flags hold the version number of your program. They are kept separate for clarity.
This holds the date the primary .texi file was last modified.

This holds the name of the month in which the primary .texi file was last modified.

The version.texi support requires the mdate-sh script; this script is supplied with Automake and automatically included when automake is invoked with the --add-missing option.

If you have multiple Texinfo files, and you want to use the version.texi feature, then you have to have a separate version file for each Texinfo file. Automake will treat any include in a Texinfo file that matches vers*.texi just as an automatically generated version file.

Sometimes an info file actually depends on more than one .texi file. For instance, in GNU Hello, hello.texi includes the file fdl.texi. You can tell Automake about these dependencies using the texi_TEXINFOS variable. Here is how GNU Hello does it:

\begin{verbatim}
info_TEXINFOS = hello.texi
hello_TEXINFOS = fdl.texi
\end{verbatim}

By default, Automake requires the file texinfo.tex to appear in the same directory as the Makefile.am file that lists the .texi files. If you used AC_CONFIG_AUX_DIR in configure.ac (see Section “Finding ‘configure’ Input” in The Autoconf Manual), then texinfo.tex is looked for there. In both cases, automake then supplies texinfo.tex if --add-missing is given, and takes care of its distribution. However, if you set the TEXINFO_TEX variable (see below), it overrides the location of the file and turns off its installation into the source as well as its distribution.

The option no-texinfo.tex can be used to eliminate the requirement for the file texinfo.tex. Use of the variable TEXINFO_TEX is preferable, however, because that allows the dvi, ps, and pdf targets to still work.

Automake generates an install-info rule; some people apparently use this. By default, info pages are installed by `make install`, so running make install-info is pointless. This can be prevented via the no-installinfo option. In this case, .info files are not installed by default, and user must request this explicitly using `make install-info`.

By default, make install-info and make install-info will try to run the install-info program (if available) to update (or create) the ${infodir}/dir index. If this is undesired, it can be prevented by exporting the AM_UPDATE_INFO_DIR variable to "no".

The following variables are used by the Texinfo build rules.

MAKEINFO The name of the program invoked to build .info files. This variable is defined by Automake. If the makeinfo program is found on the system then it will be used by default; otherwise missing will be used instead.

MAKEINFOHTML The command invoked to build .html files. Automake defines this to `${MAKEINFO} --html`.

MAKEINFOFLAGS User flags passed to each invocation of `${MAKEINFO}` and `${MAKEINFOHTML}`. This user variable (see Section 3.6 [User Variables], page 23) is not expected to
be defined in any `Makefile`; it can be used by users to pass extra flags to suit their needs.

**AM_MAKEINFOFLAGS**

Maintainer flags passed to each `makeinfo` invocation. Unlike `MAKEINFOFLAGS`, these variables are meant to be defined by maintainers in `Makefile.am`. `$(AM_MAKEINFOFLAGS)` is passed to `makeinfo` when building `.info` files; and `$(AM_MAKEINFOHTMLFLAGS)` is used when building `.html` files.

For instance, the following setting can be used to obtain one single `.html` file per manual, without node separators.

```
AM_MAKEINFOHTMLFLAGS = --no-headers --no-split
```

`AM_MAKEINFOHTMLFLAGS` defaults to `$(AM_MAKEINFOFLAGS)`. This means that defining `AM_MAKEINFOFLAGS` without defining `AM_MAKEINFOHTMLFLAGS` will impact builds of both `.info` and `.html` files.

**TEXI2DVI**
The name of the command that converts a `.texi` file into a `.dvi` file. This defaults to `texi2dvi`, a script that ships with the Texinfo package.

**TEXI2PDF**
The name of the command that translates a `.texi` file into a `.pdf` file. This defaults to `$(TEXI2DVI) --pdf --batch`.

**DVIPS**
The name of the command that builds a `.ps` file out of a `.dvi` file. This defaults to `dvips`.

**TEXINFO_TEX**
If your package has Texinfo files in many directories, you can use the variable `TEXINFO_TEX` to tell Automake where to find the canonical `texinfo.tex` for your package. The value of this variable should be the relative path from the current `Makefile.am` to `texinfo.tex`:

```
TEXINFO_TEX = ../doc/texinfo.tex
```

### 11.2 Man Pages

A package can also include man pages (but see the GNU standards on this matter, Section “Man Pages” in *The GNU Coding Standards*.) Man pages are declared using the `MANS` primary. Generally the `man_MANS` variable is used. Man pages are automatically installed in the correct subdirectory of `mandir`, based on the file extension.

File extensions such as `.1c` are handled by looking for the valid part of the extension and using that to determine the correct subdirectory of `mandir`. Valid section names are the digits ‘0’ through ‘9’, and the letters ‘l’ and ‘n’.

Sometimes developers prefer to name a man page something like `foo.man` in the source, and then rename it to have the correct suffix, for example `foo.1`, when installing the file. Automake also supports this mode. For a valid section named `section`, there is a corresponding directory named `mansectiondir`, and a corresponding `_MANS` variable. Files listed in such a variable are installed in the indicated section. If the file already has a valid suffix, then it is installed as-is; otherwise the file suffix is changed to match the section.

For instance, consider this example:

```
man1_MANS = rename.man thesame.1 alsothesame.1c
```
In this case, `rename.man` will be renamed to `rename.1` when installed, but the other files will keep their names.

By default, man pages are installed by `make install`. However, since the GNU project does not require man pages, many maintainers do not expend effort to keep the man pages up to date. In these cases, the `no-installman` option will prevent the man pages from being installed by default. The user can still explicitly install them via `make install-man`.

For fast installation, with many files it is preferable to use `mansection_MANS` over `man_MANS` as well as files that do not need to be renamed.

Man pages are not currently considered to be source, because it is not uncommon for man pages to be automatically generated. Therefore they are not automatically included in the distribution. However, this can be changed by use of the `dist_` prefix. For instance here is how to distribute and install the two man pages of GNU `cpio` (which includes both Texinfo documentation and man pages):

```bash
dist_man_MANS = cpio.1 mt.1
```

The `nobase_` prefix is meaningless for man pages and is disallowed.

Executables and manpages may be renamed upon installation (see Section 2.2.9 [Renaming], page 10). For manpages this can be avoided by use of the `notrans_` prefix. For instance, suppose an executable `foo` allowing to access a library function `foo` from the command line. The way to avoid renaming of the `foo.3` manpage is:

```bash
man_MANS = foo.1
notrans_man_MANS = foo.3
```

`notrans_` must be specified first when used in conjunction with either `dist_` or `nodist_` (see Section 14.2 [Fine-grained Distribution Control], page 99). For instance:

```bash
notrans_dist_man3_MANS = bar.3
```

## 12 What Gets Installed

Naturally, Automake handles the details of actually installing your program once it has been built. All files named by the various primaries are automatically installed in the appropriate places when the user runs `make install`.

### 12.1 Basics of Installation

A file named in a primary is installed by copying the built file into the appropriate directory. The base name of the file is used when installing.

```bash
bin_PROGRAMS = hello subdir/goodbye
```

In this example, both `hello` and `goodbye` will be installed in `$(bindir)`.

Sometimes it is useful to avoid the basename step at install time. For instance, you might have a number of header files in subdirectories of the source tree that are laid out precisely how you want to install them. In this situation you can use the `nobase_` prefix to suppress the base name step. For example:

```bash
nobase_include_HEADERS = stdio.h sys/types.h
```

will install `stdio.h` in `$(includedir)` and `types.h` in `$(includedir)/sys`.
For most file types, Automake will install multiple files at once, while avoiding command line length issues (see Section 3.4 [Length Limitations], page 22). Since some install programs will not install the same file twice in one invocation, you may need to ensure that file lists are unique within one variable such as `nobase_inlude_HEADERS` above.

You should not rely on the order in which files listed in one variable are installed. Likewise, to cater for parallel make, you should not rely on any particular file installation order even among different file types (library dependencies are an exception here).

### 12.2 The Two Parts of Install

Automake generates separate `install-data` and `install-exec` rules, in case the installer is installing on multiple machines that share directory structure—these targets allow the machine-independent parts to be installed only once. `install-exec` installs platform-dependent files, and `install-data` installs platform-independent files. The `install` target depends on both of these targets. While Automake tries to automatically segregate objects into the correct category, the Makefile.am author is, in the end, responsible for making sure this is done correctly.

Variables using the standard directory prefixes `data`, `info`, `man`, `include`, `oldinclude`, `pkgdata`, or `pkginclude` are installed by `install-data`.

Variables using the standard directory prefixes `bin`, `sbin`, `libexec`, `sysconf`, `localstate`, `lib`, or `pkglib` are installed by `install-exec`.

For instance, `data_DATA` files are installed by `install-data`, while `bin_PROGRAMS` files are installed by `install-exec`.

Any variable using a user-defined directory prefix with `exec` in the name (e.g., `myexecbin_PROGRAMS`) is installed by `install-exec`. All other user-defined prefixes are installed by `install-data`.

### 12.3 Extending Installation

It is possible to extend this mechanism by defining an `install-exec-local` or `install-data-local` rule. If these rules exist, they will be run at `make install` time. These rules can do almost anything; care is required.

Automake also supports two install hooks, `install-exec-hook` and `install-data-hook`. These hooks are run after all other install rules of the appropriate type, exec or data, have completed. So, for instance, it is possible to perform post-installation modifications using an install hook. See Section 24.1 [Extending], page 121, for some examples.

### 12.4 Staged Installs

Automake generates support for the `DESTDIR` variable in all install rules. `DESTDIR` is used during the `make install` step to relocate install objects into a staging area. Each object and path is prefixed with the value of `DESTDIR` before being copied into the install area.

Here is an example of typical DESTDIR usage:

```
mkdir /tmp/staging &&
make DESTDIR=/tmp/staging install
```

The `mkdir` command avoids a security problem if the attacker creates a symbolic link from `/tmp/staging` to a victim area; then `make` places install objects in a directory
tree built under /tmp/staging. If /gnu/bin/foo and /gnu/share/aclocal/foo.m4 are to be installed, the above command would install /tmp/staging/gnu/bin/foo and /tmp/staging/gnu/share/aclocal/foo.m4.

This feature is commonly used to build install images and packages (see Section 2.2.10 [DESTDIR], page 10).

Support for DESTDIR is implemented by coding it directly into the install rules. If your Makefile.am uses a local install rule (e.g., install-exec-local) or an install hook, then you must write that code to respect DESTDIR.

See Section “Makefile Conventions” in The GNU Coding Standards, for another usage example.

12.5 Install Rules for the User

Automake also generates rules for targets uninstall, installdirs, and install-strip.

Automake supports uninstall-local and uninstall-hook. There is no notion of separate uninstalls for “exec” and “data”, as these features would not provide additional functionality.

Note that uninstall is not meant as a replacement for a real packaging tool.

13 What Gets Cleaned

The GNU Makefile Standards specify a number of different clean rules. See Section “Standard Targets for Users” in The GNU Coding Standards.

Generally the files that can be cleaned are determined automatically by Automake. Of course, Automake also recognizes some variables that can be defined to specify additional files to clean. These variables are MOSTLYCLEANFILES, CLEANFILES, DISTCLEANFILES, and MAINTAINERCLEANFILES.

When cleaning involves more than deleting some hard-coded list of files, it is also possible to supplement the cleaning rules with your own commands. Simply define a rule for any of the mostlyclean-local, clean-local, distclean-local, or maintainer-clean-local targets (see Section 24.1 [Extending], page 121). A common case is deleting a directory, for instance, a directory created by the test suite:

    clean-local:
        -rm -rf testSubDir

Since make allows only one set of rules for a given target, a more extensible way of writing this is to use a separate target listed as a dependency:

    clean-local: clean-local-check
    .PHONY: clean-local-check
    clean-local-check:
        -rm -rf testSubDir

As the GNU Standards aren’t always explicit as to which files should be removed by which rule, we’ve adopted a heuristic that we believe was first formulated by François Pinard:

• If make built it, and it is commonly something that one would want to rebuild (for instance, a .o file), then mostlyclean should delete it.
• Otherwise, if make built it, then clean should delete it.
• If configure built it, then distclean should delete it.
• If the maintainer built it (for instance, a .info file), then maintainer-clean should delete it. However maintainer-clean should not delete anything that needs to exist in order to run './configure & make'.

We recommend that you follow this same set of heuristics in your Makefile.am.

14 What Goes in a Distribution

14.1 Basics of Distribution

The dist rule in the generated Makefile.in can be used to generate a gzipped tar file and other flavors of archive for distribution. The file is named based on the PACKAGE and VERSION variables defined by AM_INIT_AUTOMAKE (see Section 6.4 [Macros], page 44); more precisely the gzipped tar file is named ‘package-version.tar.gz’. You can use the make variable GZIP_ENV to control how gzip is run. The default setting is --best.

For the most part, the files to distribute are automatically found by Automake: all source files are automatically included in a distribution, as are all Makefile.am and Makefile.in files. Automake also has a built-in list of commonly used files that are automatically included if they are found in the current directory (either physically, or as the target of a Makefile.am rule); this list is printed by ‘automake --help’. Note that some files in this list are actually distributed only if other certain conditions hold (for example, the config.h.top and config.h.bot files are automatically distributed only if, e.g., ‘AC_CONFIG_HEADERS([config.h])’ is used in configure.ac). Also, files that are read by configure (i.e. the source files corresponding to the files specified in various Autoconf macros such as AC_CONFIG_FILES and siblings) are automatically distributed. Files included in a Makefile.am (using include) or in configure.ac (using m4_include), and helper scripts installed with ‘automake --add-missing’ are also distributed.

Still, sometimes there are files that must be distributed, but which are not covered in the automatic rules. These files should be listed in the EXTRA_DIST variable. You can mention files from subdirectories in EXTRA_DIST.

You can also mention a directory in EXTRA_DIST; in this case the entire directory will be recursively copied into the distribution. Please note that this will also copy everything in the directory, including, e.g., Subversion’s .svn private directories or CVS/RCS version control files. We recommend against using this feature.

If you define SUBDIRS, Automake will recursively include the subdirectories in the distribution. If SUBDIRS is defined conditionally (see Chapter 20 [Conditionals], page 114), Automake will normally include all directories that could possibly appear in SUBDIRS in the distribution. If you need to specify the set of directories conditionally, you can set the variable DIST_SUBDIRS to the exact list of subdirectories to include in the distribution (see Section 7.2 [Conditional Subdirectories], page 49).
14.2 Fine-grained Distribution Control

Sometimes you need tighter control over what does not go into the distribution; for instance, you might have source files that are generated and that you do not want to distribute. In this case Automake gives fine-grained control using the dist and nodist prefixes. Any primary or _SOURCES variable can be prefixed with dist_ to add the listed files to the distribution. Similarly, nodist_ can be used to omit the files from the distribution.

As an example, here is how you would cause some data to be distributed while leaving some source code out of the distribution:

```makefile
dist_data_DATA = distribute-this
bin_PROGRAMS = foo
nodist_foo_SOURCES = do-not-distribute.c
```

14.3 The dist Hook

Occasionally it is useful to be able to change the distribution before it is packaged up. If the dist-hook rule exists, it is run after the distribution directory is filled, but before the actual tar (or shar) file is created. One way to use this is for distributing files in subdirectories for which a new `Makefile.am` is overkill:

```makefile
dist-hook:
    mkdir $(distdir)/random
    cp -p $(srcdir)/random/a1 $(srcdir)/random/a2 $(distdir)/random
```

Another way to use this is for removing unnecessary files that get recursively included by specifying a directory in EXTRA_DIST:

```
EXTRA_DIST = doc

dist-hook:
    rm -rf 'find $(distdir)/doc -type d -name .svn'
```

Two variables that come handy when writing dist-hook rules are ‘$(distdir)’ and ‘$(top_distdir)’.

‘$(distdir)’ points to the directory where the dist rule will copy files from the current directory before creating the tarball. If you are at the top-level directory, then ‘distdir = $(PACKAGE)-$(VERSION)’. When used from subdirectory named foo, then ‘distdir = ../$(PACKAGE)-$(VERSION)/foo’. ‘$(distdir)’ can be a relative or absolute path, do not assume any form.

‘$(top_distdir)’ always points to the root directory of the distributed tree. At the top-level it’s equal to ‘$(distdir)’. In the foo/ subdirectory ‘top_distdir = ../$(PACKAGE)-$(VERSION)/foo’. ‘$(top_distdir)’ too can be a relative or absolute path.

Note that when packages are nested using AC_CONFIG_SUBDIRS (see Section 7.4 [Sub-packages], page 52), then ‘$(distdir)’ and ‘$(top_distdir)’ are relative to the package where `make dist` was run, not to any sub-packages involved.

14.4 Checking the Distribution

Automake also generates a distcheck rule that can be of help to ensure that a given distribution will actually work. distcheck makes a distribution, then tries to do a VPATH
build (see Section 2.2.6 [VPATH Builds], page 6), run the test suite, and finally make another tarball to ensure the distribution is self-contained.

Building the package involves running ‘./configure’. If you need to supply additional flags to configure, define them in the AM_DISTCHECK_CONFIGURE_FLAGS variable in your top-level Makefile.am. The user can still extend or override the flags provided there by defining the DISTCHECK_CONFIGURE_FLAGS variable, on the command line when invoking make.

Still, developers are encouraged to strive to make their code buildable without requiring any special configure option; thus, in general, you shouldn’t define AM_DISTCHECK_CONFIGURE_FLAGS. However, there might be few scenarios in which the use of this variable is justified. GNU m4 offers an example. GNU m4 configures by default with its experimental and seldom used "changeword" feature disabled; so in its case it is useful to have make distcheck run configure with the --with-changeword option, to ensure that the code for changeword support still compiles correctly. GNU m4 also employs the AM_DISTCHECK_CONFIGURE_FLAGS variable to stress-test the use of --program-prefix=g, since at one point the m4 build system had a bug where make installcheck was wrongly assuming it could blindly test "m4", rather than the just-installed "gm4".

If the distcheck-hook rule is defined in your top-level Makefile.am, then it will be invoked by distcheck after the new distribution has been unpacked, but before the unpacked copy is configured and built. Your distcheck-hook can do almost anything, though as always caution is advised. Generally this hook is used to check for potential distribution errors not caught by the standard mechanism. Note that distcheck-hook as well as AM_DISTCHECK_CONFIGURE_FLAGS and DISTCHECK_CONFIGURE_FLAGS are not honored in a subpackage Makefile.am, but the flags from AM_DISTCHECK_CONFIGURE_FLAGS and DISTCHECK_CONFIGURE_FLAGS are passed down to the configure script of the subpackage.

Speaking of potential distribution errors, distcheck also ensures that the distclean rule actually removes all built files. This is done by running ‘make distcleancheck’ at the end of the VPATH build. By default, distcleancheck will run distclean and then make sure the build tree has been emptied by running ‘$(distcleancheck_listfiles)’. Usually this check will find generated files that you forgot to add to the DISTCLEANFILES variable (see Chapter 13 [Clean], page 97).

The distcleancheck behavior should be OK for most packages, otherwise you have the possibility to override the definition of either the distcleancheck rule, or the ‘$(distcleancheck_listfiles)’ variable. For instance, to disable distcleancheck completely, add the following rule to your top-level Makefile.am:

```
distcleancheck:
  @:
```

If you want distcleancheck to ignore built files that have not been cleaned because they are also part of the distribution, add the following definition instead:

```
distcleancheck_listfiles = \
  find . -type f -exec sh -c 'test -f $(srcdir)/$$1 || echo $$1' \
  sh '{0}' ';' \
```

The above definition is not the default because it’s usually an error if your Makefiles cause some distributed files to be rebuilt when the user build the package. (Think about the user missing the tool required to build the file; or if the required tool is built by your
package, consider the cross-compilation case where it can’t be run.) There is an entry in the FAQ about this (see Section 28.5 [distcleancheck], page 133), make sure you read it before playing with distcleancheck_listfiles.

distcheck also checks that the uninstall rule works properly, both for ordinary and DESTDIR builds. It does this by invoking ‘make uninstall’, and then it checks the install tree to see if any files are left over. This check will make sure that you correctly coded your uninstall-related rules.

By default, the checking is done by the distuninstallcheck rule, and the list of files in the install tree is generated by ‘$(distuninstallcheck_listfiles)’ (this is a variable whose value is a shell command to run that prints the list of files to stdout).

Either of these can be overridden to modify the behavior of distcheck. For instance, to disable this check completely, you would write:

```
distuninstallcheck:
  @:
```

### 14.5 The Types of Distributions

Automake generates rules to provide archives of the project for distributions in various formats. Their targets are:

- **dist-bzip2**
  Generate a bzip2 tar archive of the distribution. bzip2 archives are frequently smaller than gzipped archives. By default, this rule makes ‘bzip2’ use a compression option of -9. To make it use a different one, set the BZIP2 environment variable. For example, ‘make dist-bzip2 BZIP2=-7’.

- **dist-gzip**
  Generate a gzip tar archive of the distribution.

- **dist-lzip**
  Generate a ‘lzip’ tar archive of the distribution. lzip archives are frequently smaller than bzip2-compressed archives.

- **dist-lzma**
  Generate an ‘lzma’ tar archive of the distribution. The ‘lzma’ format is obsolete, you should use the ‘xz’ format instead. Support for ‘lzma’-compressed archives will be removed in the next major Automake release.

- **dist-shar**
  Generate a shar archive of the distribution.

- **dist-xz**
  Generate an ‘xz’ tar archive of the distribution. xz archives are frequently smaller than bzip2-compressed archives. The ‘xz’ format displaces the obsolete ‘lzma’ format. By default, this rule makes ‘xz’ use a compression option of -e. To make it use a different one, set the XZ_OPT environment variable. For example, run this command to use the default compression ratio, but with a progress indicator: ‘make dist-xz XZ_OPT=-7e’.

- **dist-zip**
  Generate a zip archive of the distribution.
dist-tarZ

Generate a compressed tar archive of the distribution.

The rule dist (and its historical synonym dist-all) will create archives in all the enabled formats, Chapter 17 [Options], page 107. By default, only the dist-gzip target is hooked to dist.

15 Support for test suites

Automake supports three forms of test suites, the first two of which are very similar.

15.1 Simple Tests

If the variable TESTS is defined, its value is taken to be a list of programs or scripts to run in order to do the testing. Programs needing data files should look for them in srcdir (which is both an environment variable and a make variable) so they work when building in a separate directory (see Section “Build Directories” in The Autoconf Manual), and in particular for the distcheck rule (see Section 14.4 [Checking the Distribution], page 99).

For each of the TESTS, the result of execution is printed along with the test name, where PASS denotes a successful test, FAIL denotes a failed test, XFAIL an expected failure, XPASS an unexpected pass for a test that is supposed to fail, and SKIP denotes a skipped test.

The number of failures will be printed at the end of the run. If a given test program exits with a status of 77, then its result is ignored in the final count. This feature allows non-portable tests to be ignored in environments where they don’t make sense.

If the Automake option color-tests is used (see Chapter 17 [Options], page 107) and standard output is connected to a capable terminal, then the test results and the summary are colored appropriately. The user can disable colored output by setting the make variable ‘AM_COLOR_TESTS=no’, or force colored output even without a connecting terminal with ‘AM_COLOR_TESTS=always’.

Note that the semantics of some make implementations when used in parallel mode (see Section “Parallel make” in The Autoconf Manual) can cause the automatic detection of a connection to a capable terminal to fail. In that case, you can still resort to the use of ‘AM_COLOR_TESTS=always’.

The variable TESTS_ENVIRONMENT can be used to set environment variables for the test run; the environment variable srcdir is set in the rule. If all your test programs are scripts, you can also set TESTS_ENVIRONMENT to an invocation of the shell (e.g. ‘$(SHELL) -x’ can be useful for debugging the tests), or any other interpreter. For instance, the following setup may be used to run tests with Perl:

TESTS_ENVIRONMENT = $(PERL) -Mstrict -w
TESTS = foo.pl bar.pl baz.pl

Note that the parallel-tests driver provides a more elegant way to achieve the same effect, freeing the TESTS_ENVIRONMENT variable for the user to override (see Section 15.2 [Simple Tests using parallel-tests], page 103).

You may define the variable XFAIL_TESTS to a list of tests (usually a subset of TESTS) that are expected to fail. This will reverse the result of those tests.
Automake ensures that each file listed in TESTS is built before any tests are run; you can list both source and derived programs (or scripts) in TESTS; the generated rule will look both in srcdir and .. For instance, you might want to run a C program as a test. To do this you would list its name in TESTS and also in check_PROGRAMS, and then specify it as you would any other program.

Programs listed in check_PROGRAMS (and check_LIBRARIES, check_LTLIBRARIES...) are only built during make check, not during make all. You should list there any program needed by your tests that does not need to be built by make all. Note that check_PROGRAMS are not automatically added to TESTS because check_PROGRAMS usually lists programs used by the tests, not the tests themselves. Of course you can set TESTS = $(check_PROGRAMS) if all your programs are test cases.

15.2 Simple Tests using ‘parallel-tests’

The option parallel-tests (see Chapter 17 [Options], page 107) enables a test suite driver that is mostly compatible to the simple test driver described in the previous section, but provides a few more features and slightly different semantics. It features concurrent execution of tests with make -j and automatic collection of the test scripts output and summary thereof in .log files, and allows to specify inter-test dependencies, lazy reruns of tests that have not completed in a prior run, and hard errors for exceptional failures. Similar to the simple test driver, TESTS_ENVIRONMENT, AM_COLOR_TESTS, XFAIL_TESTS, and the check_* variables are honored, and the environment variable srcdir is set during test execution.

This test driver is still experimental and may undergo changes in order to satisfy additional portability requirements.

The driver operates by defining a set of make rules to create a summary log file, TEST_SUITE_LOG, which defaults to test-suite.log and requires a .log suffix. This file depends upon log files created for each single test program listed in TESTS, which in turn contain all output produced by the corresponding tests.

Each log file is created when the corresponding test has completed. The set of log files is listed in the read-only variable TEST_LOGS, and defaults to TESTS, with the executable extension if any (see Section 8.20 [EXEEXT], page 82), as well as any suffix listed in TEST_EXTENSIONS removed, and .log appended. Results are undefined if a test file name ends in several concatenated suffixes. TEST_EXTENSIONS defaults to .test; it can be overridden by the user, in which case any extension listed in it must be constituted by a dot, followed by a non-digit alphabetic character, followed by any number of alphabetic characters. For example, ‘.sh’, ‘.T’ and ‘.t1’ are valid extensions, while ‘.x-y’, ‘.6c’ and ‘.t.1’ are not.

For tests that match an extension .ext listed in TEST_EXTENSIONS, you can provide a test driver using the variable ext_LOG_COMPILER (note the upper-case extension) and pass options in AM_ext_LOG_FLAGS and allow the user to pass options in ext_LOG_FLAGS. It will cause all tests with this extension to be called with this driver. For all tests without a registered extension, the variables LOG_COMPILER, AM_LOG_FLAGS, and LOG_FLAGS may be used. For example,

\[
\begin{align*}
\text{TESTS} & = \text{foo.pl bar.py baz} \\
\text{TEST_EXTENSIONS} & = \text{.pl .py} \\
\text{PL_LOG_COMPILER} & = \text{$(PERL)$}
\end{align*}
\]
AM_PL_LOG_FLAGS = -w
PY_LOG_COMPILER = $(PYTHON)
AM_PY_LOG_FLAGS = -v
LOG_COMPILER = ./wrapper-script
AM_LOG_FLAGS = -d

will invoke `$PERL -w foo.pl`, `$PYTHON -v bar.py`, and `./wrapper-script -d baz` to produce `foo.log`, `bar.log`, and `baz.log`, respectively. The `TESTS_ENVIRONMENT` variable is still expanded before the driver, but should be reserved for the user.

As with the simple driver above, by default one status line is printed per completed test, and a short summary after the suite has completed. However, standard output and standard error of the test are redirected to a per-test log file, so that parallel execution does not produce intermingled output. The output from failed tests is collected in the `test-suite.log` file. If the variable `VERBOSE` is set, this file is output after the summary. For best results, the tests should be verbose by default now.

Previous versions of automake used to provide a `check-html` target to convert the log files to HTML. This feature is now deprecated, and will be removed in the next major Automake release, so don’t rely on it anymore.

Even in the presence of expected failures (see `XFAIL_TESTS`), there may be conditions under which a test outcome needs attention. For example, with test-driven development, you may write tests for features that you have not implemented yet, and thus mark these tests as expected to fail. However, you may still be interested in exceptional conditions, for example, tests that fail due to a segmentation violation or another error that is independent of the feature awaiting implementation. Tests can exit with an exit status of 99 to signal such a hard error. Unless the variable `DISABLE_HARD_ERRORS` is set to a nonempty value, such tests will be counted as failed.

By default, the test suite driver will run all tests, but there are several ways to limit the set of tests that are run:

- You can set the `TESTS` variable, similarly to how you can with the simple test driver from the previous section. For example, you can use a command like this to run only a subset of the tests:

  env TESTS="foo.test bar.test" make -e check

Note however that the command above will unconditionally overwrite the `test-suite.log` file, thus clobbering the recorded results of any previous testsuite run. This might be undesirable for packages whose testsuite takes long time to execute. Luckily, this problem can easily be avoided by overriding also `TEST_SUITE_LOG` at runtime; for example,

  env TEST_SUITE_LOG=partial.log TESTS="..." make -e check

will write the result of the partial testsuite runs to the `partial.log`, without touching `test-suite.log`.

- You can set the `TEST_LOGS` variable. By default, this variable is computed at `make` run time from the value of `TESTS` as described above. For example, you can use the following:

  set x subset*.log; shift
  env TEST_LOGS="foo.log $*" make -e check
The comments made above about TEST_SUITE_LOG overriding applies here too.

- By default, the test driver removes all old per-test log files before it starts running tests to regenerate them. The variable RECHECK_LOGS contains the set of log files which are removed. RECHECK_LOGS defaults to TEST_LOGS, which means all tests need to be reconsidered. By overriding this variable, you can choose which tests need to be reconsidered. For example, you can lazily rerun only those tests which are outdated, i.e., older than their prerequisite test files, by setting this variable to the empty value:

  env RECHECK_LOGS= make -e check

- You can ensure that all tests are rerun which have failed or passed unexpectedly, by running make recheck in the test directory. This convenience target will set RECHECK_LOGS appropriately before invoking the main test driver.

In order to guarantee an ordering between tests even with make -jN, dependencies between the corresponding log files may be specified through usual make dependencies. For example, the following snippet lets the test named foo-execute.test depend upon completion of the test foo-compile.test:

```
TESTS = foo-compile.test foo-execute.test
foo-execute.log: foo-compile.log
```

Please note that this ordering ignores the results of required tests, thus the test foo-execute.test is run even if the test foo-compile.test failed or was skipped beforehand. Further, please note that specifying such dependencies currently works only for tests that end in one of the suffixes listed in TEST_EXTENSIONS.

Tests without such specified dependencies may be run concurrently with parallel make -jN, so be sure they are prepared for concurrent execution.

The combination of lazy test execution and correct dependencies between tests and their sources may be exploited for efficient unit testing during development. To further speed up the edit-compile-test cycle, it may even be useful to specify compiled programs in EXTRA_PROGRAMS instead of with check_PROGRAMS, as the former allows intertwined compilation and test execution (but note that EXTRA_PROGRAMS are not cleaned automatically, see Section 3.3 [Uniform], page 20).

The variables TESTS and XFAIL_TESTS may contain conditional parts as well as configure substitutions. In the latter case, however, certain restrictions apply: substituted test names must end with a nonempty test suffix like .test, so that one of the inference rules generated by automake can apply. For literal test names, automake can generate per-target rules to avoid this limitation.

Please note that it is currently not possible to use $(srcdir)/ or $(top_srcdir)/ in the TESTS variable. This technical limitation is necessary to avoid generating test logs in the source tree and has the unfortunate consequence that it is not possible to specify distributed tests that are themselves generated by means of explicit rules, in a way that is portable to all make implementations (see Section “Make Target Lookup” in The Autoconf Manual, the semantics of FreeBSD and OpenBSD make conflict with this). In case of doubt you may want to require to use GNU make, or work around the issue with inference rules to generate the tests.
15.3 DejaGnu Tests

If dejagnu (ftp://ftp.gnu.org/gnu/dejagnu/) appears in AUTOMAKE_OPTIONS, then a dejagnu-based test suite is assumed. The variable DEJATOOL is a list of names that are passed, one at a time, as the --tool argument to runtest invocations; it defaults to the name of the package.

The variable RUNTESTDEFAULTFLAGS holds the --tool and --srcdir flags that are passed to dejagnu by default; this can be overridden if necessary.

The variables EXPECT and RUNTEST can also be overridden to provide project-specific values. For instance, you will need to do this if you are testing a compiler toolchain, because the default values do not take into account host and target names.

The contents of the variable RUNTESTFLAGS are passed to the runtest invocation. This is considered a “user variable” (see Section 3.6 [User Variables], page 23). If you need to set runtest flags in Makefile.am, you can use AM_RUNTESTFLAGS instead.

Automake will generate rules to create a local site.exp file, defining various variables detected by configure. This file is automatically read by DejaGnu. It is OK for the user of a package to edit this file in order to tune the test suite. However this is not the place where the test suite author should define new variables: this should be done elsewhere in the real test suite code. Especially, site.exp should not be distributed.

Still, if the package author has legitimate reasons to extend site.exp at make time, he can do so by defining the variable EXTRA_DEJAGNU_SITE_CONFIG; the files listed there will be considered site.exp prerequisites, and their content will be appended to it (in the same order in which they appear in EXTRA_DEJAGNU_SITE_CONFIG). Note that files are not distributed by default.

For more information regarding DejaGnu test suites, see The DejaGnu Manual.

In either case, the testing is done via 'make check'.

15.4 Install Tests

The installcheck target is available to the user as a way to run any tests after the package has been installed. You can add tests to this by writing an installcheck-local rule.

16 Rebuilding Makefiles

Automake generates rules to automatically rebuild Makefiles, configure, and other derived files like Makefile.in.

If you are using AM_MAINTAINER_MODE in configure.ac, then these automatic rebuilding rules are only enabled in maintainer mode.

Sometimes you need to run aclocal with an argument like -I to tell it where to find .m4 files. Since sometimes make will automatically run aclocal, you need a way to specify these arguments. You can do this by defining ACLOCAL_AMFLAGS; this holds arguments that are passed verbatim to aclocal. This variable is only useful in the top-level Makefile.am.

Sometimes it is convenient to supplement the rebuild rules for configure or config.status with additional dependencies. The variables CONFIGURE_DEPENDENCIES and CONFIG_STATUS_DEPENDENCIES can be used to list these extra dependencies. These
variables should be defined in all Makefiles of the tree (because these two rebuild rules are output in all them), so it is safer and easier to AC_SUBST them from configure.ac. For instance, the following statement will cause configure to be rerun each time version.sh is changed.

    AC_SUBST([CONFIG_STATUS_DEPENDENCIES], ['$\text{top}\_\text{srcdir}/version.sh'])

Note the \texttt{($\text{top}\_\text{srcdir}/)} in the file name. Since this variable is to be used in all Makefiles, its value must be sensible at any level in the build hierarchy.

Beware not to mistake CONFIGURE_DEPENDENCIES for CONFIG_STATUS_DEPENDENCIES. CONFIGURE_DEPENDENCIES adds dependencies to the configure rule, whose effect is to run autoconf. This variable should be seldom used, because automake already tracks m4_ included files. However it can be useful when playing tricky games with m4_esyscmd or similar non-recommendable macros with side effects.

CONFIG_STATUS_DEPENDENCIES adds dependencies to the config.status rule, whose effect is to run configure. This variable should therefore carry any non-standard source that may be read as a side effect of running configure, like version.sh in the example above.

Speaking of version.sh scripts, we recommend against them today. They are mainly used when the version of a package is updated automatically by a script (e.g., in daily builds). Here is what some old-style configure.acs may look like:

    AC_INIT
    . \$srcdir/version.sh
    AM_INIT_AUTOMAKE([name], \$VERSION_NUMBER)
    ...

Here, version.sh is a shell fragment that sets VERSION_NUMBER. The problem with this example is that automake cannot track dependencies (listing version.sh in CONFIG_STATUS_DEPENDENCIES, and distributing this file is up to the user), and that it uses the obsolete form of AC_INIT and AM_INIT_AUTOMAKE. Upgrading to the new syntax is not straightforward, because shell variables are not allowed in AC_INIT’s arguments. We recommend that version.sh be replaced by an M4 file that is included by configure.ac:

    m4_include([version.m4])
    AC_INIT([name], VERSION_NUMBER)
    AM_INIT_AUTOMAKE
    ...

Here version.m4 could contain something like ‘m4_define([VERSION_NUMBER], [1.2])’. The advantage of this second form is that automake will take care of the dependencies when defining the rebuild rule, and will also distribute the file automatically. An inconvenience is that autoconf will now be run each time the version number is bumped, when only configure had to be run in the previous setup.

17 Changing Automake’s Behavior

Various features of Automake can be controlled by options. Except where noted otherwise, options can be specified in one of several ways: Most options can be applied on a per-Makefile basis when listed in a special Makefile variable named AUTOMAKE_OPTIONS. Some
of these options only make sense when specified in the toplevel `Makefile.am` file. Options are applied globally to all processed `Makefile` files when listed in the first argument of `AM_INIT_AUTOMAKE` in `configure.ac`, and some options which require changes to the `configure` script can only be specified there. These are annotated below.

Currently understood options are:

`gnits`
`gnu`
`foreign`
`cygnus`

Set the strictness as appropriate. The `gnits` option also implies options `readme-alpha` and `check-news`.

`ansi2knr`
`path/ansi2knr`

Turn on the deprecated de-ANSI-fication feature (see Section 8.18 [ANSI], page 80). Note that that feature and this option will be removed in the next major Automake release.

If preceded by a path, the generated `Makefile.in` will look in the specified directory to find the `ansi2knr` program. The path should be a relative path to another directory in the same distribution (Automake does not check this).

`check-news`

Cause `make dist` to fail unless the current version number appears in the first few lines of the `NEWS` file.

`color-tests`

Cause output of the simple test suite (see Section 15.1 [Simple Tests], page 102) to be colorized on capable terminals.

`dejagnu`

Cause `dejagnu`-specific rules to be generated. See Section 15.3 [DejaGnu Tests], page 106.

`dist-bzip2`

Hook `dist-bzip2` to `dist`.

`dist-lzip`

Hook `dist-lzip` to `dist`.

`dist-lzma`

Hook `dist-lzma` to `dist`. Obsoleted by `dist-xz`.

`dist-shar`

Hook `dist-shar` to `dist`.

`dist-zip`

Hook `dist-zip` to `dist`.

`dist-tarZ`

Hook `dist-tarZ` to `dist`.

`filename-length-max=99`

Abort if file names longer than 99 characters are found during `make dist`. Such long file names are generally considered not to be portable in tarballs. See the
tar-v7 and tar-ustar options below. This option should be used in the top-level Makefile.am or as an argument of AM_INIT_AUTOMAKE in configure.ac, it will be ignored otherwise. It will also be ignored in sub-packages of nested packages (see Section 7.4 [Subpackages], page 52).

no-define
This option is meaningful only when passed as an argument to AM_INIT_AUTOMAKE. It will prevent the PACKAGE and VERSION variables from being AC_DEFINEd.

no-dependencies
This is similar to using --ignore-deps on the command line, but is useful for those situations where you don’t have the necessary bits to make automatic dependency tracking work (see Section 8.19 [Dependencies], page 81). In this case the effect is to effectively disable automatic dependency tracking.

no-dist
Don’t emit any code related to dist target. This is useful when a package has its own method for making distributions.

no-dist-gzip
Do not hook dist-gzip to dist.

no-exeext
If your Makefile.am defines a rule for target foo, it will override a rule for a target named ‘foo$(EXEEXT)’. This is necessary when EXEEXT is found to be empty. However, by default automake will generate an error for this use. The no-exeext option will disable this error. This is intended for use only where it is known in advance that the package will not be ported to Windows, or any other operating system using extensions on executables.

no-installinfo
The generated Makefile.in will not cause info pages to be built or installed by default. However, info and install-info targets will still be available. This option is disallowed at gnu strictness and above.

no-installman
The generated Makefile.in will not cause man pages to be installed by default. However, an install-man target will still be available for optional installation. This option is disallowed at gnu strictness and above.

nostdinc
This option can be used to disable the standard -I options that are ordinarily automatically provided by Automake.

no-texinfo.tex
Don’t require texinfo.tex, even if there are texinfo files in this directory.

parallel-tests
Enable test suite driver for TESTS that can run tests in parallel (see Section 15.2 [Simple Tests using parallel-tests], page 103, for more information).

readme-alpha
If this release is an alpha release, and the file README-alpha exists, then it will be added to the distribution. If this option is given, version numbers are
expected to follow one of two forms. The first form is ‘\texttt{major.minor.alpha}’, where each element is a number; the final period and number should be left off for non-alpha releases. The second form is ‘\texttt{major.minoralpha}’, where \texttt{alpha} is a letter; it should be omitted for non-alpha releases.

\textbf{silent-rules}

Enable less verbose build rules. This can be used to let build rules output status lines of the form:

\begin{verbatim}
   GEN output-file
   CC object-file
\end{verbatim}

instead of printing the command that will be executed to update \texttt{output-file} or to compile \texttt{object-file}. It can also silence \texttt{libtool} output.

For more information about how to use, enable, or disable silent rules, see Section 21.3 [Automake silent-rules Option], page 117.

\textbf{std-options}

Make the \texttt{installcheck} rule check that installed scripts and programs support the \texttt{--help} and \texttt{--version} options. This also provides a basic check that the program’s run-time dependencies are satisfied after installation.

In a few situations, programs (or scripts) have to be exempted from this test. For instance, \texttt{false} (from GNU coreutils) is never successful, even for \texttt{--help} or \texttt{--version}. You can list such programs in the variable \texttt{AM_INSTALLCHECK_STD_OPTIONS_EXEMPT}. Programs (not scripts) listed in this variable should be suffixed by \texttt{’$(EXEEXT)’} for the sake of Win32 or OS/2. For instance, suppose we build \texttt{false} as a program but \texttt{true.sh} as a script, and that neither of them support \texttt{--help} or \texttt{--version}:

\begin{verbatim}
   AUTOMAKE_OPTIONS = std-options
   bin_PROGRAMS = false ...
   bin_SCRIPTS = true.sh ...
   AM_INSTALLCHECK_STD_OPTIONS_EXEMPT = false$(EXEEXT) true.sh
\end{verbatim}

\textbf{subdir-objects}

If this option is specified, then objects are placed into the subdirectory of the build directory corresponding to the subdirectory of the source file. For instance, if the source file is \texttt{subdir/file.cxx}, then the output file would be \texttt{subdir/file.o}.

In order to use this option with C sources, you should add \texttt{AM_PROG_CC_C_O} to \texttt{configure.ac}.

\textbf{tar-v7, tar-ustar, tar-pax}

These three mutually exclusive options select the tar format to use when generating tarballs with \texttt{’make dist’}. (The tar file created is then compressed according to the set of \texttt{no-dist-gzip}, \texttt{dist-bzip2}, \texttt{dist-lzip}, \texttt{dist-xz} and \texttt{dist-tarZ} options in use.)

These options must be passed as arguments to \texttt{AM_INIT_AUTOMAKE} (see Section 6.4 [Macros], page 44) because they can require additional configure
checks. Automake will complain if it sees such options in an AUTOMAKE_OPTIONS variable.

**tar-v7** selects the old V7 tar format. This is the historical default. This antiquated format is understood by all tar implementations and supports file names with up to 99 characters. When given longer file names some tar implementations will diagnose the problem while other will generate broken tarballs or use non-portable extensions. Furthermore, the V7 format cannot store empty directories. When using this format, consider using the filename-length-max=99 option to catch file names too long.

**tar-ustar** selects the ustar format defined by POSIX 1003.1-1988. This format is believed to be old enough to be portable. It fully supports empty directories. It can store file names with up to 256 characters, provided that the file name can be split at directory separator in two parts, first of them being at most 155 bytes long. So, in most cases the maximum file name length will be shorter than 256 characters. However you may run against broken tar implementations that incorrectly handle file names longer than 99 characters (please report them to bug-automake@gnu.org so we can document this accurately).

**tar-pax** selects the new pax interchange format defined by POSIX 1003.1-2001. It does not limit the length of file names. However, this format is very young and should probably be restricted to packages that target only very modern platforms. There are moves to change the pax format in an upward-compatible way, so this option may refer to a more recent version in the future.

See Section “Controlling the Archive Format” in GNU Tar, for further discussion about tar formats.

**configure** knows several ways to construct these formats. It will not abort if it cannot find a tool up to the task (so that the package can still be built), but `make dist` will fail.

**version** A version number (e.g., ‘0.30’) can be specified. If Automake is not newer than the version specified, creation of the Makefile.in will be suppressed.

**--warnings=category**

These options behave exactly like their command-line counterpart (see Chapter 5 [automake Invocation], page 27). This allows you to enable or disable some warning categories on a per-file basis. You can also setup some warnings for your entire project; for instance, try ‘AM_INIT_AUTOMAKE([-Wall])’ in your configure.ac.

Unrecognized options are diagnosed by automake.

If you want an option to apply to all the files in the tree, you can use the AM_INIT_AUTOMAKE macro in configure.ac. See Section 6.4 [Macros], page 44.

18 Miscellaneous Rules

There are a few rules and variables that didn’t fit anywhere else.
18.1 Interfacing to etags

Automake will generate rules to generate TAGS files for use with GNU Emacs under some circumstances.

If any C, C++ or Fortran 77 source code or headers are present, then tags and TAGS rules will be generated for the directory. All files listed using the _SOURCES, _HEADERS, and _LISP primaries will be used to generate tags. Note that generated source files that are not distributed must be declared in variables like nodist_noinst_HEADERS or nodist_prog_SOURCES or they will be ignored.

A tags rule will be output at the topmost directory of a multi-directory package. When run from this topmost directory, `make tags` will generate a TAGS file that includes by reference all TAGS files from subdirectories.

The tags rule will also be generated if the variable ETAGS_ARGS is defined. This variable is intended for use in directories that contain taggable source that etags does not understand. The user can use the ETAGSFLAGS to pass additional flags to etags; AM_ETAGSFLAGS is also available for use in Makefile.am.

Here is how Automake generates tags for its source, and for nodes in its Texinfo file:

```
ETAGS_ARGS = automake.in --lang=none \ 
 --regex=’/\^@node[ \t]+\([^,]+\)/\1’ automake.texi
```

If you add file names to ETAGS_ARGS, you will probably also want to define TAGS_DEPENDENCIES. The contents of this variable are added directly to the dependencies for the tags rule.

Automake also generates a ctags rule that can be used to build vi-style tags files. The variable CTAGS is the name of the program to invoke (by default ctags); CTAGSFLAGS can be used by the user to pass additional flags, and AM_CTAGSFLAGS can be used by the Makefile.am.

Automake will also generate an ID rule that will run mkid on the source. This is only supported on a directory-by-directory basis.

Finally, Automake also emits rules to support the GNU Global Tags program (http://www.gnu.org/software/global/). The GTAGS rule runs Global Tags and puts the result in the top build directory. The variable GTAGS_ARGS holds arguments that are passed to gtags.

18.2 Handling new file extensions

It is sometimes useful to introduce a new implicit rule to handle a file type that Automake does not know about.

For instance, suppose you had a compiler that could compile .foo files to .o files. You would simply define a suffix rule for your language:

```
.foo.o:
    foocc -c -o $@ $<
```

Then you could directly use a .foo file in a _SOURCES variable and expect the correct results:

```
bin_PROGRAMS = doit
doit_SOURCES = doit.foo
```
This was the simpler and more common case. In other cases, you will have to help Automake to figure out which extensions you are defining your suffix rule for. This usually happens when your extension does not start with a dot. Then, all you have to do is to put a list of new suffixes in the `SUFFIXES` variable before you define your implicit rule.

For instance, the following definition prevents Automake from misinterpreting the `.idlC.cpp:` rule as an attempt to transform `.idlC` files into `.cpp` files.

```
SUFFIXES = .idl C.cpp
.idlC.cpp:
    # whatever
```

As you may have noted, the `SUFFIXES` variable behaves like the `.SUFFIXES` special target of `make`. You should not touch `.SUFFIXES` yourself, but use `SUFFIXES` instead and let Automake generate the suffix list for `.SUFFIXES`. Any given `SUFFIXES` go at the start of the generated suffixes list, followed by Automake generated suffixes not already in the list.

### 18.3 Support for Multilibs (deprecated, soon to be removed).

Automake used to support an obscure feature called multilibs. This feature is now deprecated, and will be removed in the next major Automake version. Still, its implementation will remain available in the `contrib/` directory of the Automake distribution, so it should be very easy for motivated users to continue to use it in their projects, if they really need to.

A multilib is a library that is built for multiple different ABIs at a single time; each time the library is built with a different target flag combination. This is only useful when the library is intended to be cross-compiled, and it is almost exclusively used for compiler support libraries.

### 19 Include

Automake supports an `include` directive that can be used to include other `Makefile` fragments when `automake` is run. Note that these fragments are read and interpreted by `automake`, not by `make`. As with conditionals, `make` has no idea that `include` is in use.

There are two forms of `include`:

```
include $(srcdir)/file
    Include a fragment that is found relative to the current source directory.

include $(top_srcdir)/file
    Include a fragment that is found relative to the top source directory.
```

Note that if a fragment is included inside a conditional, then the condition applies to the entire contents of that fragment.

Makefile fragments included this way are always distributed because they are needed to rebuild `Makefile.in`. 
20 Conditionals

Automake supports a simple type of conditionals.

These conditionals are not the same as conditionals in GNU Make. Automake conditionals are checked at configure time by the `configure` script, and affect the translation from `Makefile.in` to `Makefile`. They are based on options passed to `configure` and on results that `configure` has discovered about the host system. GNU Make conditionals are checked at make time, and are based on variables passed to the make program or defined in the `Makefile`.

Automake conditionals will work with any make program.

20.1 Usage of Conditionals

Before using a conditional, you must define it by using `AM_CONDITIONAL` in the `configure.ac` file (see Section 6.4 [Macros], page 44).

```
AM_CONDITIONAL (conditional, condition) [Macro]
The conditional name, `conditional`, should be a simple string starting with a letter and containing only letters, digits, and underscores. It must be different from ‘TRUE’ and ‘FALSE’ that are reserved by Automake.

The shell `condition` (suitable for use in a shell `if` statement) is evaluated when `configure` is run. Note that you must arrange for every `AM_CONDITIONAL` to be invoked every time `configure` is run. If `AM_CONDITIONAL` is run conditionally (e.g., in a shell `if` statement), then the result will confuse `automake`.

Conditionals typically depend upon options that the user provides to the `configure` script. Here is an example of how to write a conditional that is true if the user uses the `--enable-debug` option.

```
AC_ARG_ENABLE([debug],
[ --enable-debug Turn on debugging],
[case "${enableval}" in
  yes) debug=true ;;
  no) debug=false ;;
  *) AC_MSG_ERROR([bad value ${enableval} for --enable-debug]) ;;
  esac], [debug=false])
AM_CONDITIONAL([DEBUG], [test x$debug = xtrue])
```

Here is an example of how to use that conditional in `Makefile.am`:

```
if DEBUG
  DBG = debug
else
  DBG =
endif

noinst_PROGRAMS = $(DBG)
```

This trivial example could also be handled using `EXTRA_PROGRAMS` (see Section 8.1.4 [Conditional Programs], page 57).
You may only test a single variable in an if statement, possibly negated using ‘!’ The else statement may be omitted. Conditionals may be nested to any depth. You may specify an argument to else in which case it must be the negation of the condition used for the current if. Similarly you may specify the condition that is closed on the endif line:

```plaintext
if DEBUG
  DBG = debug
else !DEBUG
  DBG =
endif !DEBUG
```

Unbalanced conditions are errors. The if, else, and endif statements should not be indented, i.e., start on column one.

The else branch of the above two examples could be omitted, since assigning the empty string to an otherwise undefined variable makes no difference.

In order to allow access to the condition registered by AM_CONDITIONAL inside configure.ac, and to allow conditional AC_CONFIG_FILES, AM_COND_IF may be used:

```plaintext
AM_COND_IF (conditional, [if-true], [if-false])
```

If conditional is fulfilled, execute if-true, otherwise execute if-false. If either branch contains AC_CONFIG_FILES, it will cause automake to output the rules for the respective files only for the given condition.

AM_COND_IF macros may be nested when m4 quotation is used properly (see Section “M4 Quotation” in The Autoconf Manual).

Here is an example of how to define a conditional config file:

```plaintext
AM_CONDITIONAL([SHELL_WRAPPER], [test "$with_wrapper" = xtrue])
AM_COND_IF([SHELL_WRAPPER],
    [AC_CONFIG_FILES([wrapper:wrapper.in])])
```

### 20.2 Limits of Conditionals

Conditionals should enclose complete statements like variables or rules definitions. Automake cannot deal with conditionals used inside a variable definition, for instance, and is not even able to diagnose this situation. The following example would not work:

```plaintext
# This syntax is not understood by Automake
AM_CPPFLAGS = \
  -DFEATURE_A \
if WANT_DEBUG
  -DDEBUG \
endif
-DFEATURE_B
```

However the intended definition of AM_CPPFLAGS can be achieved with

```plaintext
if WANT_DEBUG
  DEBUGFLAGS = -DDEBUG
endif
AM_CPPFLAGS = -DFEATURE_A $(DEBUGFLAGS) -DFEATURE_B
```
21 Silencing make

21.1 Make is verbose by default

Normally, when executing the set of rules associated with a target, `make` prints each rule before it is executed. This behaviour, while having been in place for a long time, and being even mandated by the POSIX standard, starkly violates the “silence is golden” UNIX principle\(^8\):

When a program has nothing interesting or surprising to say, it should say nothing. Well-behaved Unix programs do their jobs unobtrusively, with a minimum of fuss and bother. Silence is golden.

In fact, while such verbosity of `make` can theoretically be useful to track bugs and understand reasons of failures right away, it can also hide warning and error messages from `make`-invoked tools, drowning them in a flood of uninteresting and seldom useful messages, and thus allowing them to go easily undetected.

This problem can be very annoying, especially for developers, who usually know quite well what’s going on behind the scenes, and for whom the verbose output from `make` ends up being mostly noise that hampers the easy detection of potentially important warning messages.

21.2 Standard and generic ways to silence make

Here we describe some common idioms/tricks to obtain a quieter `make` output, with their relative advantages and drawbacks. In the next section (Section 21.3 [Automake silent-rules Option], page 117) we’ll see how Automake can help in this respect.

- **make -s**

  This simply causes `make` not to print any rule before executing it.

  The `-s` flag is mandated by POSIX, universally supported, and its purpose and function are easy to understand.

  But it also has its serious limitations too. First of all, it embodies an “all or nothing” strategy, i.e., either everything is silenced, or nothing is; this lack of granularity can

sometimes be a fatal flaw. Moreover, when the -s flag is used, the make output might turn out to be too much terse; in case of errors, the user won’t be able to easily see what rule or command have caused them, or even, in case of tools with poor error reporting, what the errors were!

- make >/dev/null || make

Apparently, this perfectly obeys the “silence is golden” rule: warnings from stderr are passed through, output reporting is done only in case of error, and in that case it should provide a verbose-enough report to allow an easy determination of the error location and causes.

However, calling make two times in a row might hide errors (especially intermittent ones), or subtly change the expected semantic of the make calls — things these which can clearly make debugging and error assessment very difficult.

- make --no-print-directory

This is GNU make specific. When called with the --no-print-directory option, GNU make will disable printing of the working directory by invoked sub-makes (the well-known “Entering/Leaving directory ...” messages). This helps to decrease the verbosity of the output, but experience has shown that it can also often render debugging considerably harder in projects using deeply-nested make recursion.

As an aside, notice that the --no-print-directory option is automatically activated if the -s flag is used.

21.3 How Automake can help in silencing make

The tricks and idioms for silencing make described in the previous section can be useful from time to time, but we’ve seen that they all have their serious drawbacks and limitations. That’s why automake provides support for a more advanced and flexible way of obtaining quieter output from make: the silent-rules mode.

To give the gist of what silent-rules can do, here is a simple comparison between a typical make output (where silent rules are disabled) and one with silent rules enabled:

```
% cat Makefile.am
bin_PROGRAMS = foo
foo_SOURCES = main.c func.c
% cat main.c
int main (void) { return func (); } /* func used undeclared */
% cat func.c
int func (void) { int i; return i; } /* i used uninitialzed */
```

The make output is by default very verbose. This causes warnings from the compiler to be somewhat hidden, and not immediate to spot.

```
% make CFLAGS=-Wall
gcc -DPACKAGE_NAME="foo" -DPACKAGE_TARNAME="foo" ... 
-DPACKAGE_STRING="foo" 1.0" -DPACKAGE_BUGREPORT="" ... 
-DPACKAGE=""foo" -DVERSION=""1.0" -I. -Wall -MT main.o 
-DM -MP -MF .deps/main.Tpo -c -o main.o main.c
main.c: In function ‘main’:
```
main.c:3:3: warning: implicit declaration of function ‘func’
mv -f .deps/main.Tpo .deps/main.Po
gcc -DPACKAGE_NAME="foo" -DPACKAGE_TARNAME="foo" ... -DPACKAGE_STRING="foo\ 1.0" -DPACKAGE_BUGREPORT="" ... -DPACKAGE="foo" -DVERSION="1.0" -I. -Wall -MT func.o 
-MD -MP -MF .deps/func.Tpo -c -o func.o func.c
func.c: In function ‘func’:
func.c:4:3: warning: ‘i’ used uninitialized in this function
mv -f .deps/func.Tpo .deps/func.Po
gcc -Wall -o foo main.o func.o

Clean up, so that we can rebuild everything from scratch.
% make clean
test -z "foo" || rm -f foo
rm -f *.o

Silent rules enabled: the output is minimal but informative. In
particular, the warnings from the compiler stick out very clearly.
% make V=0 CFLAGS=-Wall
   CC main.o
main.c: In function ‘main’:
main.c:3:3: warning: implicit declaration of function ‘func’
   CC func.o
func.c: In function ‘func’:
func.c:4:3: warning: ‘i’ used uninitialized in this function
   CCLD foo

Also, in projects using libtool, the use of silent rules can automatically enable the
libtool’s --silent option:

% cat Makefile.am
lib_LTLIBRARIES = libx.la

% make # Both make and libtool are verbose by default.
... libtool: compile: gcc -DPACKAGE_NAME="foo" ... -DLT_OBJDIR="\libs/" 
 -I. -g -O2 -MT libx.lo -MD -MP -MF .deps/libx.Tpo -c libx.c -fPIC
 -DPIC -o .libs/libx.o
mv -f .deps/libx.Tpo .deps/libx.Plo
/bin/sh ./libtool --tag=CC --mode=link gcc -g -O2 -o libx.la -rpath
   /usr/local/lib libx.lo
libtool: link: gcc -shared .libs/libx.o -Wl,soname -Wl,libx.so.0
   -o .libs/libx.so.0.0.0
libtool: link: cd .libs && rm -f libx.so && ln -s libx.so.0.0.0 libx.so
...

% make V=0
   CC libx.lo
Let’s now see how the silent-rules mode interfaces with the package developer and the package user.

To enable the use of silent-rules in his package, a developer needs to do either of the following:

- Add the silent-rules option as argument to AM_INIT_AUTOMAKE.
- Call the AM_SILENT_RULES macro from within the configure.ac file.

It is not possible to instead specify silent-rules in a Makefile.am file.

If the developer has done either of the above, then the user of the package may influence the verbosity at configure run time as well as at make run time:

- Passing --enable-silent-rules to configure will cause build rules to be less verbose; the option --disable-silent-rules will cause normal verbose output.
- At make run time, the default chosen at configure time may be overridden: make V=1 will produce verbose output, make V=0 less verbose output.

Note that silent rules are disabled by default; the user must enable them explicitly at either configure run time or at make run time. We think that this is a good policy, since it provides the casual user with enough information to prepare a good bug report in case anything breaks.

Still, notwithstanding the rationales above, a developer who wants to make silent rules enabled by default in his own package can do so by adding a ‘yes’ argument to the AM_SILENT_RULES call in configure.ac. We advise against this approach, though.

Users who prefer to have silent rules enabled by default can edit their config.site file to make the variable enable_silent_rules default to ‘yes’. This should still allow disabling silent rules at configure time and at make time.

For portability to different make implementations, package authors are advised to not set the variable V inside the Makefile.am file, to allow the user to override the value for subdirectories as well.

The current implementation of this feature normally uses nested variable expansion ‘$(var1$(V))’, a Makefile feature that is not required by POSIX 2008 but is widely supported in practice. The silent-rules option thus turns off warnings about recursive variable expansion, which are in turn enabled by -Wportability (see Chapter 5 [automake Invocation], page 27). On the rare make implementations that do not support nested variable expansion, whether rules are silent is always determined at configure time, and cannot be overridden at make time. Future versions of POSIX are likely to require nested variable expansion, so this minor limitation should go away with time.

To extend the silent mode to your own rules, you have two choices:

- You can use the predefined variable AM_V_GEN as a prefix to commands that should output a status line in silent mode, and AM_V_at as a prefix to commands that should not output anything in silent mode. When output is to be verbose, both of these variables will expand to the empty string.
- You can add your own variables, so strings of your own choice are shown. The following snippet shows how you would define your own equivalent of AM_V_GEN:

  pkg_verbose = $(pkg_verbose_@AM_V@)
Chapter 22: The effect of --gnu and --gnits

The `--gnu` option (or `gnu` in the `AUTOMAKE_OPTIONS` variable) causes `automake` to check the following:

- The files `INSTALL`, `NEWS`, `README`, `AUTHORS`, and `ChangeLog`, plus one of `COPYING.LIB`, `COPYING.LESSER` or `COPYING`, are required at the topmost directory of the package.

If the `--add-missing` option is given, `automake` will add a generic version of the `INSTALL` file as well as the `COPYING` file containing the text of the current version of the GNU General Public License existing at the time of this Automake release (version 3 as this is written, http://www.gnu.org/copyleft/gpl.html). However, an existing `COPYING` file will never be overwritten by `automake`.

- The options `no-installman` and `no-installinfo` are prohibited.

Note that this option will be extended in the future to do even more checking; it is advisable to be familiar with the precise requirements of the GNU standards. Also, `--gnu` can require certain non-standard GNU programs to exist for use by various maintainer-only rules; for instance, in the future `pathchk` might be required for `make dist`.

The `--gnits` option does everything that `--gnu` does, and checks the following as well:

- `make installcheck` will check to make sure that the `--help` and `--version` really print a usage message and a version string, respectively. This is the `std-options` option (see Chapter 17 [Options], page 107).
- `make dist` will check to make sure the `NEWS` file has been updated to the current version.
- `VERSION` is checked to make sure its format complies with Gnits standards.
- If `VERSION` indicates that this is an alpha release, and the file `README-alpha` appears in the topmost directory of a package, then it is included in the distribution. This is done in `--gnits` mode, and no other, because this mode is the only one where version number formats are constrained, and hence the only mode where Automake can automatically determine whether `README-alpha` should be included.
- The file `THANKS` is required.
23 The effect of --cygnus

The features described in this section are deprecated; you must not use any of them in new code, and should remove their use from older but still maintained code: they will be withdrawn in a future Automake release.

Some packages, notably GNU GCC and GNU gdb, used to have a build environment originally written at Cygnus Support (subsequently renamed Cygnus Solutions, and then later purchased by Red Hat). Packages with this ancestry are sometimes referred to as “Cygnus” trees.

A Cygnus tree has slightly different rules for how a Makefile.in is to be constructed. Passing --cygnus to automake will cause any generated Makefile.in to comply with Cygnus rules.

Here are the precise effects of --cygnus:

- The foreign strictness is implied.
- The options no-installinfo, no-dependencies and no-dist are implied (see Chapter 17 [Options], page 107).
- The macro AM_MAINTAINER_MODE is required.
- Info files are always created in the build directory, and not in the source directory. Packages that don’t use the cygnus option can emulate this effect by using the no-installinfo option and listing the generated info files in the CLEANFILES variable.
- texinfo.tex is not required if a Texinfo source file is specified. The assumption is that the file will be supplied, but in a place that Automake cannot find – it is an artifact of how Cygnus packages are typically bundled. This effect can be emulated in packages not using the cygnus option with a proper definition of the TEXINFO_TEX variable (see Section 11.1 [Texinfo], page 92).
- Certain tools will be searched for in the build tree as well as in the user’s PATH. These tools are runtest, expect, makeinfo and texi2dvi.
- The check target doesn’t depend on all.

24 When Automake Isn’t Enough

In some situations, where Automake is not up to one task, one has to resort to handwritten rules or even handwritten Makefiles.

24.1 Extending Automake Rules

With some minor exceptions (for example _PROGRAMS variables, TESTS, or XFAIL_TESTS) being rewritten to append ‘$(EXEEXT)’), the contents of a Makefile.am is copied to Makefile.in verbatim.

These copying semantics mean that many problems can be worked around by simply adding some make variables and rules to Makefile.am. Automake will ignore these additions.

Since a Makefile.in is built from data gathered from three different places (Makefile.am, configure.ac, and automake itself), it is possible to have conflicting
definitions of rules or variables. When building `Makefile.in` the following priorities are respected by `automake` to ensure the user always has the last word:

- User defined variables in `Makefile.am` have priority over variables `AC_SUBST`ed from `configure.ac`, and `AC_SUBST`ed variables have priority over `automake`-defined variables.
- As far as rules are concerned, a user-defined rule overrides any `automake`-defined rule for the same target.

These overriding semantics make it possible to fine tune some default settings of Automake, or replace some of its rules. Overriding Automake rules is often inadvisable, particularly in the topmost directory of a package with subdirectories. The `-Woverride` option (see Chapter 5 [automake Invocation], page 27) comes in handy to catch overridden definitions.

Note that Automake does not make any distinction between rules with commands and rules that only specify dependencies. So it is not possible to append new dependencies to an `automake`-defined target without redefining the entire rule.

However, various useful targets have a ‘-local’ version you can specify in your `Makefile.am`. Automake will supplement the standard target with these user-supplied targets.

The targets that support a local version are `all`, `info`, `dvi`, `ps`, `pdf`, `html`, `check`, `install-data`, `install-dvi`, `install-exec`, `install-html`, `install-info`, `install-pdf`, `install-ps`, `uninstall`, `installdirs`, `installcheck` and the various `clean` targets (`mostlyclean`, `clean`, `distclean`, and `maintainer-clean`).

Note that there are no `uninstall-exec-local` or `uninstall-data-local` targets; just use `uninstall-local`. It doesn’t make sense to uninstall just data or just executables.

For instance, here is one way to erase a subdirectory during `make clean` (see Chapter 13 [Clean], page 97).

```
   clean-local:
       -rm -rf testSubDir
```

You may be tempted to use `install-data-local` to install a file to some hard-coded location, but you should avoid this (see Section 28.10 [Hard-Coded Install Paths], page 143).

With the `-local` targets, there is no particular guarantee of execution order; typically, they are run early, but with parallel make, there is no way to be sure of that.

In contrast, some rules also have a way to run another rule, called a hook; hooks are always executed after the main rule’s work is done. The hook is named after the principal target, with ‘-hook’ appended. The targets allowing hooks are `install-data`, `install-exec`, `uninstall`, `dist`, and `distcheck`.

For instance, here is how to create a hard link to an installed program:

```
   install-exec-hook:
       ln $(DESTDIR)$(bindir)/program$(EXEEXT) $(DESTDIR)$(bindir)/proglink$(EXEEXT)
```

Although cheaper and more portable than symbolic links, hard links will not work everywhere (for instance, OS/2 does not have `ln`). Ideally you should fall back to `cp -p`
when `ln` does not work. An easy way, if symbolic links are acceptable to you, is to add `AC_PROG_LN_S` to `configure.ac` (see Section “Particular Program Checks” in *The Autoconf Manual*) and use `$(LN_S)` in `Makefile.am`.

For instance, here is how you could install a versioned copy of a program using `$(LN_S)`:

```
install-exec-hook:
  cd $(DESTDIR)$(bindir) && \\
  mv -f prog$(EXEEXT) prog-$(VERSION)$(EXEEXT) && \\
  $(LN_S) prog-$(VERSION)$(EXEEXT) prog$(EXEEXT)
```

Note that we rename the program so that a new version will erase the symbolic link, not the real binary. Also we `cd` into the destination directory in order to create relative links.

When writing `install-exec-hook` or `install-data-hook`, please bear in mind that the exec/data distinction is based on the installation directory, not on the primary used (see Section 12.2 [The Two Parts of Install], page 96). So a `foo_SCRIPTS` will be installed by `install-data`, and a `barexec_SCRIPTS` will be installed by `install-exec`. You should define your hooks consequently.

### 24.2 Third-Party Makefiles

In most projects all `Makefiles` are generated by Automake. In some cases, however, projects need to embed subdirectories with handwritten `Makefiles`. For instance, one subdirectory could be a third-party project with its own build system, not using Automake.

It is possible to list arbitrary directories in `SUBDIRS` or `DIST_SUBDIRS` provided each of these directories has a `Makefile` that recognizes all the following recursive targets.

When a user runs one of these targets, that target is run recursively in all subdirectories. This is why it is important that even third-party `Makefiles` support them.

<table>
<thead>
<tr>
<th>target</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>all</code></td>
<td>Compile the entire package. This is the default target in Automake-generated <code>Makefiles</code>, but it does not need to be the default in third-party <code>Makefiles</code>.</td>
</tr>
<tr>
<td><code>distdir</code></td>
<td>Copy files to distribute into <code>$(distdir)</code>, before a tarball is constructed. Of course this target is not required if the <code>no-dist</code> option (see Chapter 17 [Options], page 107) is used.</td>
</tr>
<tr>
<td><code>install</code></td>
<td>Install or uninstall files (see Chapter 12 [Install], page 95).</td>
</tr>
<tr>
<td><code>install-data</code></td>
<td></td>
</tr>
<tr>
<td><code>install-exec</code></td>
<td></td>
</tr>
<tr>
<td><code>uninstall</code></td>
<td></td>
</tr>
</tbody>
</table>
install-dvi
install-html
install-info
install-ps
install-pdf

Install only some specific documentation format (see Section 11.1 [Texinfo], page 92).

installdirs

Create install directories, but do not install any files.

check
installcheck

Check the package (see Chapter 15 [Tests], page 102).

mostlyclean
clean
distclean
maintainer-clean

Cleaning rules (see Chapter 13 [Clean], page 97).

dvi
pdf
ps
info
html

Build the documentation in various formats (see Section 11.1 [Texinfo], page 92).

tags
ctags

Build TAGS and CTAGS (see Section 18.1 [Tags], page 112).

If you have ever used Gettext in a project, this is a good example of how third-party
Makefiles can be used with Automake. The Makefiles gettextize puts in the po/ and
intl/ directories are handwritten Makefiles that implement all these targets. That way
they can be added to SUBDIRS in Automake packages.

Directories that are only listed in DIST_SUBDIRS but not in SUBDIRS need only the
distclean, maintainer-clean, and distdir rules (see Section 7.2 [Conditional Subdirectories], page 49).

Usually, many of these rules are irrelevant to the third-party subproject, but they are
required for the whole package to work. It’s OK to have a rule that does nothing, so if
you are integrating a third-party project with no documentation or tag support, you could
simply augment its Makefile as follows:

EMPTY_AUTOMAKE_TARGETS = dvi pdf ps info html tags ctags
.PHONY: $(EMPTY_AUTOMAKE_TARGETS)
$(EMPTY_AUTOMAKE_TARGETS):

Another aspect of integrating third-party build systems is whether they support VPATH
builds (see Section 2.2.6 [VPATH Builds], page 6). Obviously if the subpackage does not sup-
port VPATH builds the whole package will not support VPATH builds. This in turns means
that ‘make distcheck’ will not work, because it relies on VPATH builds. Some people can
live without this (actually, many Automake users have never heard of `make distcheck`). Other people may prefer to revamp the existing Makefiles to support VPATH. Doing so does not necessarily require Automake, only Autoconf is needed (see Section “Build Directories” in The Autoconf Manual). The necessary substitutions: `@srcdir@`, `@top_srcdir@`, and `@top_builddir@` are defined by configure when it processes a Makefile (see Section “Preset Output Variables” in The Autoconf Manual), they are not computed by the Makefile like the aforementioned `$(distdir)` and `$(top_distdir)` variables.

It is sometimes inconvenient to modify a third-party Makefile to introduce the above required targets. For instance, one may want to keep the third-party sources untouched to ease upgrades to new versions.

Here are two other ideas. If GNU make is assumed, one possibility is to add to that subdirectory a GNUmakefile that defines the required targets and includes the third-party Makefile. For this to work in VPATH builds, GNUmakefile must lie in the build directory; the easiest way to do this is to write a GNUmakefile.in instead, and have it processed with AC_CONFIG_FILES from the outer package. For example if we assume Makefile defines all targets except the documentation targets, and that the check target is actually called test, we could write GNUmakefile (or GNUmakefile.in) like this:

```bash
# First, include the real Makefile
include Makefile

# Then, define the other targets needed by Automake Makefiles.
.PHONY: dvi pdf ps info html check
dvi pdf ps info html:
check: test
```

A similar idea that does not use include is to write a proxy Makefile that dispatches rules to the real Makefile, either with `$(MAKE) -f Makefile.real $(AM_MAKEFLAGS) target` (if it’s OK to rename the original Makefile) or with `cd subdir && $(MAKE) $(AM_MAKEFLAGS) target` (if it’s OK to store the subdirectory project one directory deeper). The good news is that this proxy Makefile can be generated with Automake. All we need are -local targets (see Section 24.1 [Extending], page 121) that perform the dispatch. Of course the other Automake features are available, so you could decide to let Automake perform distribution or installation. Here is a possible Makefile.am:

```
all-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) all
check-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) test
clean-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) clean

# Assuming the package knows how to install itself
install-data-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) install-data
install-exec-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) install-exec
uninstall-local:
    cd subdir && $(MAKE) $(AM_MAKEFLAGS) uninstall
```
# Distribute files from here.
EXTRA_DIST = subdir/Makefile subdir/program.c ...

Pushing this idea to the extreme, it is also possible to ignore the subproject build system and build everything from this proxy Makefile.am. This might sound very sensible if you need VPATH builds but the subproject does not support them.

## 25 Distributing Makefile.ins

Automake places no restrictions on the distribution of the resulting Makefile.ins. We still encourage software authors to distribute their work under terms like those of the GPL, but doing so is not required to use Automake.

Some of the files that can be automatically installed via the `--add-missing` switch do fall under the GPL. However, these also have a special exception allowing you to distribute them with your package, regardless of the licensing you choose.

## 26 Automake API Versioning

New Automake releases usually include bug fixes and new features. Unfortunately they may also introduce new bugs and incompatibilities. This makes four reasons why a package may require a particular Automake version.

Things get worse when maintaining a large tree of packages, each one requiring a different version of Automake. In the past, this meant that any developer (and sometimes users) had to install several versions of Automake in different places, and switch `$PATH` appropriately for each package.

Starting with version 1.6, Automake installs versioned binaries. This means you can install several versions of Automake in the same `$prefix`, and can select an arbitrary Automake version by running `automake-1.6` or `automake-1.7` without juggling with `$PATH`. Furthermore, Makefile’s generated by Automake 1.6 will use `automake-1.6` explicitly in their rebuild rules.

The number ‘1.6’ in `automake-1.6` is Automake’s API version, not Automake’s version. If a bug fix release is made, for instance Automake 1.6.1, the API version will remain 1.6. This means that a package that works with Automake 1.6 should also work with 1.6.1; after all, this is what people expect from bug fix releases.

If your package relies on a feature or a bug fix introduced in a release, you can pass this version as an option to Automake to ensure older releases will not be used. For instance, use this in your `configure.ac`:

```
AM_INIT_AUTOMAKE([1.6.1]) dnl Require Automake 1.6.1 or better.
```

or, in a particular `Makefile.am`:

```
AUTOMAKE_OPTIONS = 1.6.1 # Require Automake 1.6.1 or better.
```

Automake will print an error message if its version is older than the requested version.
What is in the API

Automake’s programming interface is not easy to define. Basically it should include at least all documented variables and targets that a Makefile.am author can use, any behavior associated with them (e.g., the places where ‘-hook’ s are run), the command line interface of automake and aclocal, ...

What is not in the API

Every undocumented variable, target, or command line option, is not part of the API. You should avoid using them, as they could change from one version to the other (even in bug fix releases, if this helps to fix a bug).

If it turns out you need to use such an undocumented feature, contact automake@gnu.org and try to get it documented and exercised by the test-suite.

27 Upgrading a Package to a Newer Automake Version

Automake maintains three kind of files in a package.

- aclocal.m4
- Makefile.ins
- auxiliary tools like install-sh or py-compile

aclocal.m4 is generated by aclocal and contains some Automake-supplied M4 macros. Auxiliary tools are installed by ‘automake --add-missing’ when needed. Makefile.ins are built from Makefile.am by automake, and rely on the definitions of the M4 macros put in aclocal.m4 as well as the behavior of the auxiliary tools installed.

Because all these files are closely related, it is important to regenerate all of them when upgrading to a newer Automake release. The usual way to do that is

aclocal # with any option needed (such a -I m4)
autconf
automake --add-missing --force-missing

or more conveniently:

autoreconf -vfi

The use of --force-missing ensures that auxiliary tools will be overridden by new versions (see Chapter 5 [automake Invocation], page 27).

It is important to regenerate all these files each time Automake is upgraded, even between bug fixes releases. For instance, it is not unusual for a bug fix to involve changes to both the rules generated in Makefile.in and the supporting M4 macros copied to aclocal.m4.

Presently automake is able to diagnose situations where aclocal.m4 has been generated with another version of aclocal. However it never checks whether auxiliary scripts are up-to-date. In other words, automake will tell you when aclocal needs to be rerun, but it will never diagnose a missing --force-missing.

Before upgrading to a new major release, it is a good idea to read the file NEWS. This file lists all changes between releases: new features, obsolete constructs, known incompatibilities, and workarounds.
28 Frequently Asked Questions about Automake

This chapter covers some questions that often come up on the mailing lists.

28.1 CVS and generated files

Background: distributed generated Files
Packages made with Autoconf and Automake ship with some generated files like configure or Makefile.in. These files were generated on the developer’s host and are distributed so that end-users do not have to install the maintainer tools required to rebuild them. Other generated files like Lex scanners, Yacc parsers, or Info documentation, are usually distributed on similar grounds.

Automake outputs rules in Makefiles to rebuild these files. For instance, make will run autoconf to rebuild configure whenever configure.ac is changed. This makes development safer by ensuring a configure is never out-of-date with respect to configure.ac.

As generated files shipped in packages are up-to-date, and because tar preserves timestamps, these rebuild rules are not triggered when a user unpacks and builds a package.

Background: CVS and Timestamps
Unless you use CVS keywords (in which case files must be updated at commit time), CVS preserves timestamp during ‘cvs commit’ and ‘cvs import -d’ operations.

When you check out a file using ‘cvs checkout’ its timestamp is set to that of the revision that is being checked out.

However, during cvs update, files will have the date of the update, not the original timestamp of this revision. This is meant to make sure that make notices sources files have been updated.

This timestamp shift is troublesome when both sources and generated files are kept under CVS. Because CVS processes files in lexical order, configure.ac will appear newer than configure after a cvs update that updates both files, even if configure was newer than configure.ac when it was checked in. Calling make will then trigger a spurious rebuild of configure.

Living with CVS in Autoconfiscated Projects
There are basically two clans amongst maintainers: those who keep all distributed files under CVS, including generated files, and those who keep generated files out of CVS.

All Files in CVS
- The CVS repository contains all distributed files so you know exactly what is distributed, and you can checkout any prior version entirely.
- Maintainers can see how generated files evolve (for instance, you can see what happens to your Makefile.ins when you upgrade Automake and make sure they look OK).
- Users do not need the autotools to build a checkout of the project, it works just like a released tarball.
• If users use `cvs update` to update their copy, instead of `cvs checkout` to fetch a fresh one, timestamps will be inaccurate. Some rebuild rules will be triggered and attempt to run developer tools such as `autoconf` or `automake`.

Actually, calls to such tools are all wrapped into a call to the `missing` script discussed later (see Section 28.2 [maintainer-mode], page 130). `missing` will take care of fixing the timestamps when these tools are not installed, so that the build can continue.

• In distributed development, developers are likely to have different versions of the maintainer tools installed. In this case, rebuilds triggered by timestamp lossage will lead to spurious changes to generated files. There are several solutions to this:

  • All developers should use the same versions, so that the rebuilt files are identical to files in CVS. (This starts to be difficult when each project you work on uses different versions.)
  • Or people use a script to fix the timestamp after a checkout (the GCC folks have such a script).
  • Or `configure.ac` uses `AM_MAINTAINER_MODE`, which will disable all these rebuild rules by default. This is further discussed in Section 28.2 [maintainer-mode], page 130.

• Although we focused on spurious rebuilds, the converse can also happen. CVS's timestamp handling can also let you think an out-of-date file is up-to-date.

For instance, suppose a developer has modified `Makefile.am` and has rebuilt `Makefile.in`, and then decides to do a last-minute change to `Makefile.am` right before checking in both files (without rebuilding `Makefile.in` to account for the change).

This last change to `Makefile.am` makes the copy of `Makefile.in` out-of-date. Since CVS processes files alphabetically, when another developer `cvs update`s his or her tree, `Makefile.in` will happen to be newer than `Makefile.am`. This other developer will not see that `Makefile.in` is out-of-date.

Generated Files out of CVS

One way to get CVS and `make` working peacefully is to never store generated files in CVS, i.e., do not CVS-control files that are `Makefile` targets (also called derived files).

This way developers are not annoyed by changes to generated files. It does not matter if they all have different versions (assuming they are compatible, of course). And finally, timestamps are not lost, changes to sources files can't be missed as in the `Makefile.am/Makefile.in` example discussed earlier.

The drawback is that the CVS repository is not an exact copy of what is distributed and that users now need to install various development tools (maybe even specific versions) before they can build a checkout. But, after all, CVS's job is versioning, not distribution.

Allowing developers to use different versions of their tools can also hide bugs during distributed development. Indeed, developers will be using (hence testing) their own generated files, instead of the generated files that will be released actually. The developer who prepares the tarball might be using a version of the tool that produces bogus output (for instance a non-portable C file), something other developers could have noticed if they weren't using their own versions of this tool.
Chapter 28: Frequently Asked Questions about Automake

Third-party Files

Another class of files not discussed here (because they do not cause timestamp issues) are files that are shipped with a package, but maintained elsewhere. For instance, tools like gettextize and autopoint (from Gettext) or libtoolize (from Libtool), will install or update files in your package.

These files, whether they are kept under CVS or not, raise similar concerns about version mismatch between developers’ tools. The Gettext manual has a section about this, see Section “Integrating with CVS” in GNU gettext tools.

28.2 missing and AM_MAINTAINER_MODE

missing

The missing script is a wrapper around several maintainer tools, designed to warn users if a maintainer tool is required but missing. Typical maintainer tools are autoconf, automake, bison, etc. Because file generated by these tools are shipped with the other sources of a package, these tools shouldn’t be required during a user build and they are not checked for in configure.

However, if for some reason a rebuild rule is triggered and involves a missing tool, missing will notice it and warn the user. Besides the warning, when a tool is missing, missing will attempt to fix timestamps in a way that allows the build to continue. For instance, missing will touch configure if autoconf is not installed. When all distributed files are kept under version control, this feature of missing allows a user with no maintainer tools to build a package off its version control repository, bypassing any timestamp inconsistency (implied by e.g. ‘cvs update’ or ‘git clone’).

If the required tool is installed, missing will run it and won’t attempt to continue after failures. This is correct during development: developers love fixing failures. However, users with wrong versions of maintainer tools may get an error when the rebuild rule is spuriously triggered, halting the build. This failure to let the build continue is one of the arguments of the AM_MAINTAINER_MODE advocates.

AM_MAINTAINER_MODE

AM_MAINTAINER_MODE allows you to choose whether the so called "rebuild rules" should be enabled or disabled. With AM_MAINTAINER_MODE([enable]), they are enabled by default, otherwise they are disabled by default. In the latter case, if you have AM_MAINTAINER_MODE in configure.ac, and run ‘./configure & make’, then make will *never* attempt to rebuild configure, Makefile.in, Lex or Yacc outputs, etc. I.e., this disables build rules for files that are usually distributed and that users should normally not have to update.

The user can override the default setting by passing either ‘--enable-maintainer-mode’ or ‘--disable-maintainer-mode’ to configure.

People use AM_MAINTAINER_MODE either because they do not want their users (or themselves) annoyed by timestamps lossage (see Section 28.1 [CVS], page 128), or because they simply can’t stand the rebuild rules and prefer running maintainer tools explicitly.

AM_MAINTAINER_MODE also allows you to disable some custom build rules conditionally. Some developers use this feature to disable rules that need exotic tools that users may not have available.
Several years ago François Pinard pointed out several arguments against this
AM_MAINTAINER_MODE macro. Most of them relate to insecurity. By removing dependencies
you get non-dependable builds: changes to sources files can have no effect on generated
files and this can be very confusing when unnoticed. He adds that security shouldn’t be
reserved to maintainers (what --enable-maintainer-mode suggests), on the contrary. If
one user has to modify a Makefile.am, then either Makefile.in should be updated or a
warning should be output (this is what Automake uses missing for) but the last thing you
want is that nothing happens and the user doesn’t notice it (this is what happens when
rebuild rules are disabled by AM_MAINTAINER_MODE).

Jim Meyering, the inventor of the AM_MAINTAINER_MODE macro was swayed by François’s
arguments, and got rid of AM_MAINTAINER_MODE in all of his packages.

Still many people continue to use AM_MAINTAINER_MODE, because it helps them working
on projects where all files are kept under version control, and because missing isn’t enough
if you have the wrong version of the tools.

28.3 Why doesn’t Automake support wildcards?

Developers are lazy. They would often like to use wildcards in Makefile.ams, so that
they would not need to remember to update Makefile.ams every time they add, delete, or
rename a file.

There are several objections to this:

• When using CVS (or similar) developers need to remember they have to run ‘cvs add’
or ‘cvs rm’ anyway. Updating Makefile.am accordingly quickly becomes a reflex.
  Conversely, if your application doesn’t compile because you forgot to add a file in
  Makefile.am, it will help you remember to ‘cvs add’ it.
• Using wildcards makes it easy to distribute files by mistake. For instance, some code
  a developer is experimenting with (a test case, say) that should not be part of the
distribution.
• Using wildcards it’s easy to omit some files by mistake. For instance, one developer
  creates a new file, uses it in many places, but forgets to commit it. Another developer
  then checks out the incomplete project and is able to run ‘make dist’ successfully, even
  though a file is missing. By listing files, ‘make dist’ will complain.
• Wildcards are not portable to some non-GNU make implementations, e.g., NetBSD
  make will not expand globs such as ‘*’ in prerequisites of a target.
• Finally, it’s really hard to forget to add a file to Makefile.am: files that are not listed
  in Makefile.am are not compiled or installed, so you can’t even test them.

Still, these are philosophical objections, and as such you may disagree, or find enough
value in wildcards to dismiss all of them. Before you start writing a patch against Automake
to teach it about wildcards, let’s see the main technical issue: portability.

Although ‘$(wildcard ...)’ works with GNU make, it is not portable to other make
implementations.

The only way Automake could support $(wildcard ...) is by expending $(wildcard ...
) when automake is run. The resulting Makefile.ins would be portable since they
would list all files and not use ‘$(wildcard ...)’. However that means developers would
need to remember to run automake each time they add, delete, or rename files.
Compared to editing `Makefile.am`, this is a very small gain. Sure, it’s easier and faster to type ‘`automake; make`’ than to type ‘`emacs Makefile.am; make`’. But nobody bothered enough to write a patch to add support for this syntax. Some people use scripts to generate file lists in `Makefile.am` or in separate `Makefile` fragments.

Even if you don’t care about portability, and are tempted to use ‘`$(wildcard ...)`’ anyway because you target only GNU Make, you should know there are many places where Automake needs to know exactly which files should be processed. As Automake doesn’t know how to expand ‘`$(wildcard ...)`’, you cannot use it in these places. ‘`$(wildcard ...)`’ is a black box comparable to `AC_SUBSTed` variables as far Automake is concerned.

You can get warnings about ‘`$(wildcard ...)`’ constructs using the `-Wportability` flag.

**28.4 Limitations on File Names**

Automake attempts to support all kinds of file names, even those that contain unusual characters or are unusually long. However, some limitations are imposed by the underlying operating system and tools.

Most operating systems prohibit the use of the null byte in file names, and reserve ‘/’ as a directory separator. Also, they require that file names are properly encoded for the user’s locale. Automake is subject to these limits.

Portable packages should limit themselves to POSIX file names. These can contain ASCII letters and digits, ‘_’, ‘.’, and ‘-’. File names consist of components separated by ‘/’. File name components cannot begin with ‘-’.

Portable POSIX file names cannot contain components that exceed a 14-byte limit, but nowadays it’s normally safe to assume the more-generous XOPEN limit of 255 bytes. POSIX limits file names to 255 bytes (XOPEN allows 1023 bytes), but you may want to limit a source tarball to file names of 99 bytes to avoid interoperability problems with old versions of `tar`.

If you depart from these rules (e.g., by using non-ASCII characters in file names, or by using lengthy file names), your installers may have problems for reasons unrelated to Automake. However, if this does not concern you, you should know about the limitations imposed by Automake itself. These limitations are undesirable, but some of them seem to be inherent to underlying tools like Autoconf, Make, M4, and the shell. They fall into three categories: install directories, build directories, and file names.

The following characters:

```
newline " # $ ' 
```

should not appear in the names of install directories. For example, the operand of `configure`’s `--prefix` option should not contain these characters.

Build directories suffer the same limitations as install directories, and in addition should not contain the following characters:

```
& @ \ 
```

For example, the full name of the directory containing the source files should not contain these characters.

Source and installation file names like `main.c` are limited even further: they should conform to the POSIX/XOPEN rules described above. In addition, if you plan to port
to non-POSIX environments, you should avoid file names that differ only in case (e.g., `makefile` and `Makefile`). Nowadays it is no longer worth worrying about the 8.3 limits of DOS file systems.

### 28.5 Files left in build directory after distclean

This is a diagnostic you might encounter while running `make distcheck`.

As explained in Section 14.4 [Checking the Distribution], page 99, `make distcheck` attempts to build and check your package for errors like this one.

`make distcheck` will perform a VPATH build of your package (see Section 2.2.6 [VPATH Builds], page 6), and then call `make distclean`. Files left in the build directory after `make distclean` has run are listed after this error.

This diagnostic really covers two kinds of errors:

- files that are forgotten by distclean;
- distributed files that are erroneously rebuilt.

The former left-over files are not distributed, so the fix is to mark them for cleaning (see Chapter 13 [Clean], page 97), this is obvious and doesn’t deserve more explanations.

The latter bug is not always easy to understand and fix, so let’s proceed with an example. Suppose our package contains a program for which we want to build a man page using `help2man`. GNU `help2man` produces simple manual pages from the `--help` and `--version` output of other commands (see Section “Overview” in *The Help2man Manual*). Because we don’t want to force our users to install `help2man`, we decide to distribute the generated man page using the following setup.

```make
# This Makefile.am is bogus.
bin_PROGRAMS = foo
foo_SOURCES = foo.c
dist_man_MANS = foo.1

foo.1: foo$(EXEEXT)
    help2man --output=foo.1 ./foo$(EXEEXT)
```

This will effectively distribute the man page. However, `make distcheck` will fail with:

```
ERROR: files left in build directory after distclean:
./foo.1
```

Why was `foo.1` rebuilt? Because although distributed, `foo.1` depends on a non-distributed built file: `foo$(EXEEXT)`. `foo$(EXEEXT)` is built by the user, so it will always appear to be newer than the distributed `foo.1`.

`make distcheck` caught an inconsistency in our package. Our intent was to distribute `foo.1` so users do not need to install `help2man`, however since this rule causes this file to be always rebuilt, users *do* need `help2man`. Either we should ensure that `foo.1` is not rebuilt by users, or there is no point in distributing `foo.1`.

More generally, the rule is that distributed files should never depend on non-distributed built files. If you distribute something generated, distribute its sources.
One way to fix the above example, while still distributing \texttt{foo.1} is to not depend on \texttt{foo$(EXEEXT)}). For instance, assuming \texttt{foo --version} and \texttt{foo --help} do not change unless \texttt{foo.c} or \texttt{configure.ac} change, we could write the following \texttt{Makefile.am}:

```plaintext
bin_PROGRAMS = foo
foo_SOURCES = foo.c
dist_man_MANS = foo.1

foo.1: foo.c $(top_srcdir)/configure.ac
       $(MAKE) $(AM_MAKEFLAGS) foo$(EXEEXT)
       help2man --output=foo.1 ./foo$(EXEEXT)
```

This way, \texttt{foo.1} will not get rebuilt every time \texttt{foo$(EXEEXT)} changes. The \texttt{make} call makes sure \texttt{foo$(EXEEXT)} is up-to-date before \texttt{help2man}. Another way to ensure this would be to use separate directories for binaries and man pages, and set \texttt{SUBDIRS} so that binaries are built before man pages.

We could also decide not to distribute \texttt{foo.1}. In this case it’s fine to have \texttt{foo.1} dependent upon \texttt{foo$(EXEEXT)}, since both will have to be rebuilt. However it would be impossible to build the package in a cross-compilation, because building \texttt{foo.1} involves an \textit{execution} of \texttt{foo$(EXEEXT)}.

Another context where such errors are common is when distributed files are built by tools that are built by the package. The pattern is similar:

```plaintext
distributed-file: built-tools distributed-sources
       build-command
```

should be changed to

```plaintext
distributed-file: distributed-sources
       $(MAKE) $(AM_MAKEFLAGS) built-tools
       build-command
```

or you could choose not to distribute \texttt{distributed-file}, if cross-compilation does not matter.

The points made through these examples are worth a summary:

- Distributed files should never depend upon non-distributed built files.
- Distributed files should be distributed with all their dependencies.
- If a file is \textit{intended} to be rebuilt by users, then there is no point in distributing it.

For desperate cases, it’s always possible to disable this check by setting \texttt{distcleancheck_listfiles} as documented in Section 14.4 [Checking the Distribution], page 99. Make sure you do understand the reason why ‘\texttt{make distcheck}’ complains before you do this. \texttt{distcleancheck_listfiles} is a way to \textit{hide} errors, not to fix them. You can always do better.

### 28.6 Flag Variables Ordering

What is the difference between \texttt{AM_CFLAGS}, \texttt{CFLAGS}, and
Chapter 28: Frequently Asked Questions about Automake

mumble_CFLAGS?

Why does automake output CPPFLAGS after AM_CPPFLAGS on compile lines? Shouldn’t it be the converse?

My configure adds some warning flags into CXXFLAGS. In one Makefile.am I would like to append a new flag, however if I put the flag into AM_CXXFLAGS it is prepended to the other flags, not appended.

Compile Flag Variables

This section attempts to answer all the above questions. We will mostly discuss CPPFLAGS in our examples, but actually the answer holds for all the compile flags used in Automake: CCASFLAGS, CFLAGS, CPPFLAGS, CXXFLAGS, FCFLAGS, FFLAGS, GCJFLAGS, LDFLAGS, LFLAGS, LIBTOOLFLAGS, OBJCFLAGS, RFLAGS, UPCFLAGS, and YFLAGS.

CPPFLAGS, AM_CPPFLAGS, and mumble_CPPFLAGS are three variables that can be used to pass flags to the C preprocessor (actually these variables are also used for other languages like C++ or preprocessed Fortran). CPPFLAGS is the user variable (see Section 3.6 [User Variables], page 23), AM_CPPFLAGS is the Automake variable, and mumble_CPPFLAGS is the variable specific to the mumble target (we call this a per-target variable, see Section 8.4 [Program and Library Variables], page 65).

Automake always uses two of these variables when compiling C sources files. When compiling an object file for the mumble target, the first variable will be mumble_CPPFLAGS if it is defined, or AM_CPPFLAGS otherwise. The second variable is always CPPFLAGS.

In the following example,

```plaintext
bin_PROGRAMS = foo bar
foo_SOURCES = xyz.c
bar_SOURCES = main.c
foo_CPPFLAGS = -DFOO
AM_CPPFLAGS = -DBAZ
```

xyz.o will be compiled with `$\{foo_CPPFLAGS\} $\{CPPFLAGS\}` (because xyz.o is part of the foo target), while main.o will be compiled with `$\{AM_CPPFLAGS\} $\{CPPFLAGS\}` (because there is no per-target variable for target bar).

The difference between mumble_CPPFLAGS and AM_CPPFLAGS being clear enough, let’s focus on CPPFLAGS. CPPFLAGS is a user variable, i.e., a variable that users are entitled to modify in order to compile the package. This variable, like many others, is documented at the end of the output of `configure --help`.

For instance, someone who needs to add `/home/my/usr/include` to the C compiler’s search path would configure a package with

```plaintext
./configure CPPFLAGS='--I /home/my/usr/include'
```

and this flag would be propagated to the compile rules of all Makefiles.

It is also not uncommon to override a user variable at make-time. Many installers do this with prefix, but this can be useful with compiler flags too. For instance, if, while debugging a C++ project, you need to disable optimization in one specific object file, you can run something like

```plaintext
rm file.o
```
make CXXFLAGS=-00 file.o
make

The reason ‘$(CPPFLAGS)’ appears after ‘$(AM_CPPFLAGS)’ or ‘$(mumble_CPPFLAGS)’ in the compile command is that users should always have the last say. It probably makes more sense if you think about it while looking at the ‘CXXFLAGS=-00’ above, which should supersede any other switch from AM_CXXFLAGS or mumble_CXXFLAGS (and this of course replaces the previous value of CXXFLAGS).

You should never redefine a user variable such as CPPFLAGS in Makefile.am. Use ‘automake -Woverride’ to diagnose such mistakes. Even something like

CPPFLAGS = -DDATADIR="$(datadir)" @CPPFLAGS@ is erroneous. Although this preserves configure’s value of CPPFLAGS, the definition of DATADIR will disappear if a user attempts to override CPPFLAGS from the make command line.

AM_CPPFLAGS = -DDATADIR="$(datadir)"

is all that is needed here if no per-target flags are used.

You should not add options to these user variables within configure either, for the same reason. Occasionally you need to modify these variables to perform a test, but you should reset their values afterwards. In contrast, it is OK to modify the ‘AM_’ variables within configure if you AC_SUBST them, but it is rather rare that you need to do this, unless you really want to change the default definitions of the ‘AM_’ variables in all Makefiles.

What we recommend is that you define extra flags in separate variables. For instance, you may write an Autoconf macro that computes a set of warning options for the C compiler, and AC_SUBST them in WARNINGCFLAGS; you may also have an Autoconf macro that determines which compiler and which linker flags should be used to link with library libfoo, and AC_SUBST these in LIBFOOCFLAGS and LIBFOOLDFLAGS. Then, a Makefile.am could use these variables as follows:

AM_CFLAGS = $(WARNINGCFLAGS)
bin_PROGRAMS = prog1 prog2
prog1_SOURCES = ...
prog2_SOURCES = ...
prog2_CFLAGS = $(LIBFOOCFLAGS) $(AM_CFLAGS)
prog2_LDFLAGS = $(LIBFOOLDFLAGS)

In this example both programs will be compiled with the flags substituted into ‘$(WARNINGCFLAGS)’, and prog2 will additionally be compiled with the flags required to link with libfoo.

Note that listing AM_CFLAGS in a per-target CFLAGS variable is a common idiom to ensure that AM_CFLAGS applies to every target in a Makefile.in.

Using variables like this gives you full control over the ordering of the flags. For instance, if there is a flag in $(WARNINGCFLAGS) that you want to negate for a particular target, you can use something like ‘prog1_CFLAGS = $(AM_CFLAGS) -no-flag’. If all these flags had been forcefully appended to CFLAGS, there would be no way to disable one flag. Yet another reason to leave user variables to users.

Finally, we have avoided naming the variable of the example LIBFOO_LDFLAGS (with an underscore) because that would cause Automake to think that this is actually a per-target variable (like mumble_LDFLAGS) for some non-declared LIBFOO target.
Chapter 28: Frequently Asked Questions about Automake

Other Variables

There are other variables in Automake that follow similar principles to allow user options. For instance, Texinfo rules (see Section 11.1 [Texinfo], page 92) use MAKEINFOFLAGS and AM_MAKEINFOFLAGS. Similarly, DejaGnu tests (see Section 15.3 [DejaGnu Tests], page 106) use RUNTESTDEFAULTFLAGS and AM_RUNTESTDEFAULTFLAGS. The tags and ctags rules (see Section 18.1 [Tags], page 112) use ETAGSFLAGS, AM_ETAGSFLAGS, CTAGSFLAGS, and AM_CTAGSFLAGS. Java rules (see Section 10.4 [Java], page 89) use JAVACFLAGS and AM_JAVACFLAGS. None of these rules support per-target flags (yet).

To some extent, even AM_MAKEFLAGS (see Section 7.1 [Subdirectories], page 48) obeys this naming scheme. The slight difference is that MAKEFLAGS is passed to sub-makes implicitly by make itself.

However you should not think that all variables ending with FLAGS follow this convention. For instance, DISTCHECK_CONFIGURE_FLAGS (see Section 14.4 [Checking the Distribution], page 99) and ACLOCAL_AMFLAGS (see Chapter 16 [Rebuilding], page 106, and Section 6.3.4 [Local Macros], page 41), are two variables that are only useful to the maintainer and have no user counterpart.

ARFLAGS (see Section 8.2 [A Library], page 58) is usually defined by Automake and has neither AM_ nor per-target cousin.

Finally you should not think that the existence of a per-target variable implies the existence of an AM_ variable or of a user variable. For instance, the mumble_LDADD per-target variable overrides the makefile-wide LDADD variable (which is not a user variable), and mumble_LIBADD exists only as a per-target variable. See Section 8.4 [Program and Library Variables], page 65.

28.7 Why are object files sometimes renamed?

This happens when per-target compilation flags are used. Object files need to be renamed just in case they would clash with object files compiled from the same sources, but with different flags. Consider the following example.

```
bin_PROGRAMS = true false
ture_SOURCES = generic.c
ture_CPPFLAGS = -DEXIT_CODE=0
false_SOURCES = generic.c
false_CPPFLAGS = -DEXIT_CODE=1
```

Obviously the two programs are built from the same source, but it would be bad if they shared the same object, because generic.o cannot be built with both ‘-DEXIT_CODE=0’ and ‘-DEXIT_CODE=1’. Therefore automake outputs rules to build two different objects: true-generic.o and false-generic.o.

automake doesn’t actually look whether source files are shared to decide if it must rename objects. It will just rename all objects of a target as soon as it sees per-target compilation flags used.

It’s OK to share object files when per-target compilation flags are not used. For instance, true and false will both use version.o in the following example.

```
AM_CPPFLAGS = -DVERSION=1.0
bin_PROGRAMS = true false
```
true_SOURCES = true.c version.c
false_SOURCES = false.c version.c

Note that the renaming of objects is also affected by the _SHORTNAME variable (see Section 8.4 [Program and Library Variables], page 65).

28.8 Per-Object Flags Emulation

One of my source files needs to be compiled with different flags. How do I do?

Automake supports per-program and per-library compilation flags (see Section 8.4 [Program and Library Variables], page 65, and Section 28.6 [Flag Variables Ordering], page 134). With this you can define compilation flags that apply to all files compiled for a target. For instance, in

bin_PROGRAMS = foo
foo_SOURCES = foo.c foo.h bar.c bar.h main.c
foo_CFLAGS = -some -flags

foo-foo.o, foo-bar.o, and foo-main.o will all be compiled with `~some ~flags`. (If you wonder about the names of these object files, see Section 28.7 [Renamed Objects], page 137.) Note that foo_CFLAGS gives the flags to use when compiling all the C sources of the program foo, it has nothing to do with foo.c or foo-foo.o specifically.

What if foo.c needs to be compiled into foo.o using some specific flags, that none of the other files requires? Obviously per-program flags are not directly applicable here. Something like per-object flags are expected, i.e., flags that would be used only when creating foo-foo.o. Automake does not support that, however this is easy to simulate using a library that contains only that object, and compiling this library with per-library flags.

bin_PROGRAMS = foo
foo_SOURCES = bar.c bar.h main.c
foo_CFLAGS = -some -flags
foo_LDADD = libfoo.a
noinst_LIBRARIES = libfoo.a
libfoo_a_SOURCES = foo.c foo.h
libfoo_a_CFLAGS = -some -other -flags

Here foo-bar.o and foo-main.o will all be compiled with `~some ~flags`, while libfoo_a-foo.o will be compiled using `~some ~other ~flags`. Eventually, all three objects will be linked to form foo.

This trick can also be achieved using Libtool convenience libraries, for instance `noinst_LTLIBRARIES = libfoo.la` (see Section 8.3.5 [Libtool Convenience Libraries], page 61).

Another tempting idea to implement per-object flags is to override the compile rules automake would output for these files. Automake will not define a rule for a target you have defined, so you could think about defining the `foo-foo.o: foo.c` rule yourself. We recommend against this, because this is error prone. For instance, if you add such a rule to the first example, it will break the day you decide to remove foo_CFLAGS (because foo.c will then be compiled as foo.o instead of foo-foo.o, see Section 28.7 [Renamed Objects], page 137). Also in order to support dependency tracking, the two .o/.obj extensions, and
all the other flags variables involved in a compilation, you will end up modifying a copy of
the rule previously output by automake for this file. If a new release of Automake generates
a different rule, your copy will need to be updated by hand.

28.9 Handling Tools that Produce Many Outputs

This section describes a make idiom that can be used when a tool produces multiple output
files. It is not specific to Automake and can be used in ordinary Makefiles.

Suppose we have a program called foo that will read one file called data.foo and produce
two files named data.c and data.h. We want to write a Makefile rule that captures this
one-to-two dependency.

The naive rule is incorrect:
# This is incorrect.
data.c data.h: data.foo
  foo data.foo

What the above rule really says is that data.c and data.h each depend on data.foo, and
can each be built by running ‘foo data.foo’. In other words it is equivalent to:
# We do not want this.
data.c: data.foo
  foo data.foo
data.h: data.foo
  foo data.foo

which means that foo can be run twice. Usually it will not be run twice, because make
implementations are smart enough to check for the existence of the second file after the
first one has been built; they will therefore detect that it already exists. However there are
a few situations where it can run twice anyway:
• The most worrying case is when running a parallel make. If data.c and data.h are
  built in parallel, two ‘foo data.foo’ commands will run concurrently. This is harmful.
• Another case is when the dependency (here data.foo) is (or depends upon) a phony
target.

A solution that works with parallel make but not with phony dependencies is the follow-
ing:
data.c data.h: data.foo
  foo data.foo
data.h: data.c

The above rules are equivalent to
 data.c: data.foo
  foo data.foo
data.h: data.foo data.c
  foo data.foo

therefore a parallel make will have to serialize the builds of data.c and data.h, and will
detect that the second is no longer needed once the first is over.

Using this pattern is probably enough for most cases. However it does not scale easily to
more output files (in this scheme all output files must be totally ordered by the dependency
relation), so we will explore a more complicated solution.
Another idea is to write the following:

```
# There is still a problem with this one.
data.c: data.foo
    foo data.foo
data.h: data.c
```

The idea is that `foo data.foo` is run only when `data.c` needs to be updated, but we further state that `data.h` depends upon `data.c`. That way, if `data.h` is required and `data.foo` is out of date, the dependency on `data.c` will trigger the build.

This is almost perfect, but suppose we have built `data.h` and `data.c`, and then we erase `data.h`. Then, running `make data.h` will not rebuild `data.h`. The above rules just state that `data.c` must be up-to-date with respect to `data.foo`, and this is already the case.

What we need is a rule that forces a rebuild when `data.h` is missing. Here it is:

```
data.c: data.foo
    foo data.foo
data.h: data.c
## Recover from the removal of $@
    @if test -f $@; then ;; else \n        rm -f data.c; \
        $(MAKE) $(AM_MAKEFLAGS) data.c; \
    fi
```

The above scheme can be extended to handle more outputs and more inputs. One of the outputs is selected to serve as a witness to the successful completion of the command, it depends upon all inputs, and all other outputs depend upon it. For instance, if `foo` should additionally read `data.bar` and also produce `data.w` and `data.x`, we would write:

```
data.c: data.foo data.bar
    foo data.foo data.bar
data.h data.w data.x: data.c
## Recover from the removal of $@
    @if test -f $@; then ;; else \n        rm -f data.c; \
        $(MAKE) $(AM_MAKEFLAGS) data.c; \
    fi
```

However there are now three minor problems in this setup. One is related to the time-stamp ordering of `data.h`, `data.w`, `data.x`, and `data.c`. Another one is a race condition if a parallel `make` attempts to run multiple instances of the recover block at once. Finally, the recursive rule breaks `make -n` when run with GNU `make` (as well as some other `make` implementations), as it may remove `data.h` even when it should not (see Section “How the `MAKE` Variable Works” in The GNU Make Manual).

Let us deal with the first problem. `foo` outputs four files, but we do not know in which order these files are created. Suppose that `data.h` is created before `data.c`. Then we have a weird situation. The next time `make` is run, `data.h` will appear older than `data.c`, the second rule will be triggered, a shell will be started to execute the `if...fi` command, but actually it will just execute the `then` branch, that is: nothing. In other words, because the witness we selected is not the first file created by `foo`, `make` will start a shell to do nothing each time it is run.
A simple riposte is to fix the timestamps when this happens.

```bash
data.c: data.foo data.bar
  foo data.foo data.bar
data.h data.w data.x: data.c
  @if test -f $@; then \n    touch $@; \n  else \n  ## Recover from the removal of $@
    rm -f data.c; \n    $(MAKE) $(AM_MAKEFLAGS) data.c; \n  fi
```

Another solution is to use a different and dedicated file as witness, rather than using any of foo’s outputs.

```bash
data.stamp: data.foo data.bar
  @rm -f data.tmp
  @touch data.tmp
  foo data.foo data.bar
  @mv -f data.tmp $@
data.c data.h data.w data.x: data.stamp
  ## Recover from the removal of $@
  @if test -f $@; then ;; else \n    rm -f data.stamp; \n    $(MAKE) $(AM_MAKEFLAGS) data.stamp; \n  fi
```

data.tmp is created before foo is run, so it has a timestamp older than output files output by foo. It is then renamed to data.stamp after foo has run, because we do not want to update data.stamp if foo fails.

This solution still suffers from the second problem: the race condition in the recover rule. If, after a successful build, a user erases data.c and data.h, and runs `make -j`, then make may start both recover rules in parallel. If the two instances of the rule execute `$(MAKE) $(AM_MAKEFLAGS) data.stamp` concurrently the build is likely to fail (for instance, the two rules will create data.tmp, but only one can rename it).

Admittedly, such a weird situation does not arise during ordinary builds. It occurs only when the build tree is mutilated. Here data.c and data.h have been explicitly removed without also removing data.stamp and the other output files. make clean; make will always recover from these situations even with parallel makes, so you may decide that the recover rule is solely to help non-parallel make users and leave things as-is. Fixing this requires some locking mechanism to ensure only one instance of the recover rule rebuilds data.stamp. One could imagine something along the following lines.

```bash
data.c data.h data.w data.x: data.stamp
  ## Recover from the removal of $@
  @if test -f $@; then ;; else \n    trap 'rm -rf data.lock data.stamp' 1 2 13 15; \n  ## mkdir is a portable test-and-set
    if mkdir data.lock 2>/dev/null; then \n```
## This code is being executed by the first process.
rm -f data.stamp; \
$(MAKE) $(AM_MAKEFLAGS) data.stamp; \
result=$$?; rm -rf data.lock; exit $$result; \
else \
## This code is being executed by the follower processes.
## Wait until the first process is done.
while test -d data.lock; do sleep 1; done; \
## Succeed if and only if the first process succeeded.
test -f data.stamp; \
fi; \
fi

Using a dedicated witness, like data.stamp, is very handy when the list of output files
is not known beforehand. As an illustration, consider the following rules to compile many
*.el files into *.elc files in a single command. It does not matter how ELFILES is defined
(as long as it is not empty: empty targets are not accepted by POSIX).

ELFILES = one.el two.el three.el ...
ELCFILES = $(ELFILES:=c)

elc-stamp: $(ELFILES)
@rm -f elc-temp
@touch elc-temp
$(elisp_comp) $(ELFILES)
@mv -f elc-temp $@

$(ELCFILES): elc-stamp
@if test -f $@; then ;; else \n## Recover from the removal of $@
trap 'rm -rf elc-lock elc-stamp' 1 2 13 15; \nif mkdir elc-lock 2>/dev/null; then \n## This code is being executed by the first process.
rm -f elc-stamp; \
$(MAKE) $(AM_MAKEFLAGS) elc-stamp; \
rmdir elc-lock; \
else \
## This code is being executed by the follower processes.
## Wait until the first process is done.
while test -d elc-lock; do sleep 1; done; \
## Succeed if and only if the first process succeeded.
test -f elc-stamp; exit $$?; \nfi; \
fi

These solutions all still suffer from the third problem, namely that they break the promise
that `make -n` should not cause any actual changes to the tree. For those solutions that do
not create lock files, it is possible to split the recover rules into two separate recipe com-
mands, one of which does all work but the recursion, and the other invokes the recursive
‘$(MAKE)’. The solutions involving locking could act upon the contents of the ‘MAKEFLAGS’ variable, but parsing that portably is not easy (see Section “The Make Macro MAKEFLAGS” in The Autoconf Manual). Here is an example:

```
ELFILES = one.el two.el three.el ...
ELCFILES = $(ELFILES:=c)

elc-stamp: $(ELFILES)
   @rm -f elc-temp
   @touch elc-temp
   $(elisp_comp) $(ELFILES)
   @mv -f elc-temp $@

$(ELCFILES): elc-stamp
   ## Recover from the removal of $@
   @dry=; for f in x $$MAKEFLAGS; do 
     case $$f in
       *=*|--*);; 
       *n*) dry=::; 
     esac; 
   done; 
   if test -f $@; then :; else 
     $$dry trap 'rm -rf elc-lock elc-stamp' 1 2 13 15; 
     if $$dry mkdir elc-lock 2>/dev/null; then 
       ## This code is being executed by the first process.
       $$dry rm -f elc-temp; 
       $(MAKE) $(AM_MAKEFLAGS) elc-stamp; 
       $$dry rmdir elc-lock; 
     else 
       ## This code is being executed by the follower processes.
       ## Wait until the first process is done.
       while test -d elc-lock && test -z "$$dry"; do 
         sleep 1; 
         done; 
       ## Succeed if and only if the first process succeeded.
       $$dry test -f elc-temp; exit $$?; 
     fi; 
   fi
```

For completeness it should be noted that GNU `make` is able to express rules with multiple output files using pattern rules (see Section “Pattern Rule Examples” in The GNU Make Manual). We do not discuss pattern rules here because they are not portable, but they can be convenient in packages that assume GNU `make`.

### 28.10 Installing to Hard-Coded Locations

My package needs to install some configuration file. I tried to use the following rule, but `make distcheck` fails. Why?
# Do not do this.

install-data-local:
    $(INSTALL_DATA) $(srcdir)/afile $(DESTDIR)/etc/afile

My package needs to populate the installation directory of another package at install-time. I can easily compute that installation directory in configure, but if I install files therein, ‘make distcheck’ fails. How else should I do?

These two setups share their symptoms: ‘make distcheck’ fails because they are installing files to hard-coded paths. In the later case the path is not really hard-coded in the package, but we can consider it to be hard-coded in the system (or in whichever tool that supplies the path). As long as the path does not use any of the standard directory variables (‘$(prefix)’, ‘$(bindir)’, ‘$(datadir)’, etc.), the effect will be the same: user-installations are impossible.

As a (non-root) user who wants to install a package, you usually have no right to install anything in /usr or /usr/local. So you do something like ‘./configure --prefix ~/usr’ to install a package in your own ~/usr tree.

If a package attempts to install something to some hard-coded path (e.g., /etc/afile), regardless of this --prefix setting, then the installation will fail. ‘make distcheck’ performs such a --prefix installation, hence it will fail too.

Now, there are some easy solutions.

The above install-data-local example for installing /etc/afile would be better replaced by

    sysconf_DATA = afile

by default sysconfdir will be ‘$(prefix)/etc’, because this is what the GNU Standards require. When such a package is installed on an FHS compliant system, the installer will have to set ‘--sysconfdir=/etc’. As the maintainer of the package you should not be concerned by such site policies: use the appropriate standard directory variable to install your files so that the installer can easily redefine these variables to match their site conventions.

Installing files that should be used by another package is slightly more involved. Let’s take an example and assume you want to install a shared library that is a Python extension module. If you ask Python where to install the library, it will answer something like this:

    % python -c 'from distutils import sysconfig;
    print sysconfig.get_python_lib(1,0)'

    /usr/lib/python2.5/site-packages

If you indeed use this absolute path to install your shared library, non-root users will not be able to install the package, hence distcheck fails.

Let’s do better. The ‘sysconfig.get_python_lib()’ function actually accepts a third argument that will replace Python’s installation prefix.

    % python -c 'from distutils import sysconfig;
    print sysconfig.get_python_lib(1,0,"${exec_prefix}" )'

    ${exec_prefix}/lib/python2.5/site-packages

You can also use this new path. If you do

• root users can install your package with the same --prefix as Python (you get the behavior of the previous attempt)
• non-root users can install your package too, they will have the extension module in a place that is not searched by Python but they can work around this using environment variables (and if you installed scripts that use this shared library, it’s easy to tell Python were to look in the beginning of your script, so the script works in both cases).

The AM_PATH_PYTHON macro uses similar commands to define ‘$(pythondir)’ and ‘$(pyexecdir)’ (see Section 10.5 [Python], page 90).

Of course not all tools are as advanced as Python regarding that substitution of prefix. So another strategy is to figure the part of the installation directory that must be preserved. For instance, here is how AM_PATH_LISPDIR (see Section 10.1 [Emacs Lisp], page 88) computes ‘$(lispdir)’:

```
$EMACS -batch -q -eval '(while load-path
 (princ (concat (car load-path) "\n")))
(setq load-path (cdr load-path)))' >conftest.out
lispdir='sed -n -e 's,/$,,'
-e '/.*/lib\/*/emacs\*/site-lisp$/{ s,\/*/lib\/*\(emacs\*/site-lisp\)\$,\{libdir\}/\1,;p;q; }',
-e '/.*/share\/*/emacs\*/site-lisp$/{ s,\/*/share\/*\(emacs\*/site-lisp\),\{datarootdir\}/\1,;p;q; }',
conftest.out'
```

I.e., it just picks the first directory that looks like */lib/*/emacs/*/site-lisp or */share/*/emacs/*/site-lisp in the search path of emacs, and then substitutes ‘${libdir}’ or ‘${datadir}’ appropriately.

The emacs case looks complicated because it processes a list and expects two possible layouts, otherwise it’s easy, and the benefits for non-root users are really worth the extra sed invocation.

### 28.11 Debugging Make Rules

The rules and dependency trees generated by automake can get rather complex, and leave the developer head-scratching when things don’t work as expected. Besides the debug options provided by the make command (see Section “Options Summary” in The GNU Make Manual), here’s a couple of further hints for debugging makefiles generated by automake effectively:

• If less verbose output has been enabled in the package with the ‘silent-rules’ option (see Chapter 17 [Options], page 107), you can use make V=1 to see the commands being executed.

• make -n can help show what would be done without actually doing it. Note however, that this will still execute commands prefixed with ‘+’, and, when using GNU make, commands that contain the strings ‘${MAKE}’ or ‘${MAKE}’ (see Section “Instead of Execution” in The GNU Make Manual). Typically, this is helpful to show what recursive rules would do, but it means that, in your own rules, you should not mix such
recursion with actions that change any files. Furthermore, note that GNU make will update prerequisites for the Makefile file itself even with -n (see Section “Remaking Makefiles” in The GNU Make Manual).

- echo 'print: ; @echo "$(VAR)"' | make -f Makefile -f - print can be handy to examine the expanded value of variables. You may need to use a target other than ‘print’ if that is already used or a file with that name exists.

- http://bashdb.sourceforge.net/remake/ provides a modified GNU make command called remake that copes with complex GNU make-specific Makefiles and allows to trace execution, examine variables, and call rules interactively, much like a debugger.

### 28.12 Reporting Bugs

Most nontrivial software has bugs. Automake is no exception. Although we cannot promise we can or will fix a bug, and we might not even agree that it is a bug, we want to hear about problems you encounter. Often we agree they are bugs and want to fix them.

To make it possible for us to fix a bug, please report it. In order to do so effectively, it helps to know when and how to do it.

Before reporting a bug, it is a good idea to see if it is already known. You can look at the GNU Bug Tracker (http://debbugs.gnu.org/) and the bug-automake mailing list archives (http://lists.gnu.org/archive/html/bug-automake/) for previous bug reports. We previously used a Gnats database (http://sourceware.org/cgi-bin/gnatsweb.pl?database=automake) for bug tracking, so some bugs might have been reported there already. Please do not use it for new bug reports, however.

If the bug is not already known, it should be reported. It is very important to report bugs in a way that is useful and efficient. For this, please familiarize yourself with How to Report Bugs Effectively (http://www.chiark.greenend.org.uk/~sgtatham/bugs.html) and How to Ask Questions the Smart Way (http://catb.org/~esr/faqs/smart-questions.html). This helps you and developers to save time which can then be spent on fixing more bugs and implementing more features.

For a bug report, a feature request or other suggestions, please send email to bug-automake@gnu.org. This will then open a new bug in the bug tracker (http://debbugs.gnu.org/automake). Be sure to include the versions of Autoconf and Automake that you use. Ideally, post a minimal Makefile.am and configure.ac that reproduces the problem you encounter. If you have encountered test suite failures, please attach the tests/test-suite.log file.

---

9 Automake’s ‘dist’ and ‘distcheck’ rules had a bug in this regard in that they created directories even with -n, but this has been fixed in Automake 1.11.
29 History of Automake

This chapter presents various aspects of the history of Automake. The exhausted reader can safely skip it; this will be more of interest to nostalgic people, or to those curious to learn about the evolution of Automake.

29.1 Timeline

1994-09-19 First CVS commit.
If we can trust the CVS repository, David J. MacKenzie (djm) started working on Automake (or AutoMake, as it was spelt then) this Monday.
The first version of the automake script looks as follows.

```sh
#!/bin/sh

status=0

for makefile
  do
    if test ! -f ${makefile}.am; then
      echo "automake: ${makefile}.am: No such honkin' file"
      status=1
      continue
    fi

    exec 4> ${makefile}.in
  done
```

From this you can already see that Automake will be about reading `.am` files and producing `.in` files. You cannot see anything else, but if you also know that David is the one who created Autoconf two years before you can guess the rest.

Several commits follow, and by the end of the day Automake is reported to work for GNU fileutils and GNU m4.
The modus operandi is the one that is still used today: variable assignments in `Makefile.am` files trigger injections of precanned `Makefile` fragments into the generated `Makefile.in`. The use of `Makefile` fragments was inspired by the 4.4BSD `make` and include files, however Automake aims to be portable and to conform to the GNU standards for `Makefile` variables and targets.

At this point, the most recent release of Autoconf is version 1.11, and David is preparing to release Autoconf 2.0 in late October. As a matter of fact, he will barely touch Automake after September.

At this point Automake is a 200 line portable shell script, plus 332 lines of `Makefile` fragments. In the README, David states his ambivalence between “portable shell” and “more appropriate language”: 
I wrote it keeping in mind the possibility of it becoming an Autoconf macro, so it would run at configure-time. That would slow configuration down a bit, but allow users to modify the Makefile.am without needing to fetch the AutoMake package. And, the Makefile.in files wouldn’t need to be distributed. But all of AutoMake would. So I might reimplement AutoMake in Perl, m4, or some other more appropriate language.

Automake is described as “an experimental Makefile generator”. There is no documentation. Adventurous users are referred to the examples and patches needed to use Automake with GNU m4 1.3, fileutils 3.9, time 1.6, and development versions of find and indent.

These examples seem to have been lost. However at the time of writing (10 years later in September, 2004) the FSF still distributes a package that uses this version of Automake: check out GNU termutils 2.0.

1995-11-12 Tom Tromey’s first commit.

After one year of inactivity, Tom Tromey takes over the package. Tom was working on GNU cpio back then, and doing this just for fun, having trouble finding a project to contribute to. So while hacking he wanted to bring the Makefile.in up to GNU standards. This was hard, and one day he saw Automake on \texttt{ftp://alpha.gnu.org/}, grabbed it and tried it out.

Tom didn’t talk to djm about it until later, just to make sure he didn’t mind if he made a release. He did a bunch of early releases to the Gnits folks.

Gnits was (and still is) totally informal, just a few GNU friends who François Pinard knew, who were all interested in making a common infrastructure for GNU projects, and shared a similar outlook on how to do it. So they were able to make some progress. It came along with Autoconf and extensions thereof, and then Automake from David and Tom (who were both gnitsians). One of their ideas was to write a document paralleling the GNU standards, that was more strict in some ways and more detailed. They never finished the GNITS standards, but the ideas mostly made their way into Automake.

1995-11-23 Automake 0.20

Besides introducing automatic dependency tracking (see Section 29.2 [Dependency Tracking Evolution], page 158), this version also supplies a 9-page manual.

At this time \texttt{aclocal} and \texttt{AM_INIT_AUTOMAKE} did not exist, so many things had to be done by hand. For instance, here is what a configure.in (this is the former name of the \texttt{configure.ac} we use today) must contain in order to use Automake 0.20:

```plaintext
PACKAGE=cpio
VERSION=2.3.911
AC_DEFINE_UNQUOTED(PACKAGE, "$PACKAGE")
AC_DEFINE_UNQUOTED(VERSION, "$VERSION")
AC_SUBST(PACKAGE)
AC_SUBST(VERSION)
AC_ARG_PROGRAM
```
AC_PROG_INSTALL

(Today all of the above is achieved by AC_INIT and AM_INIT_AUTOMAKE.)

Here is how programs are specified in Makefile.am:

```
PROGRAMS = hello
hello_SOURCES = hello.c
```

This looks pretty much like what we do today, except the PROGRAMS variable has no directory prefix specifying where hello should be installed: all programs are installed in `$BINDIR'`. LIBPROGRAMS can be used to specify programs that must be built but not installed (it is called noinst_PROGRAMS nowadays).

Programs can be built conditionally using AC_SUBSTitutions:

```
PROGRAMS = @progs@
AM_PROGRAMS = foo bar baz
```

(`AM_PROGRAMS has since then been renamed to EXTRA_PROGRAMS.)

Similarly scripts, static libraries, and data can be built and installed using the LIBRARIES, SCRIPTS, and DATA variables. However LIBRARIES were treated a bit specially in that Automake did automatically supply the `lib' and `.a' prefixes. Therefore to build `libcpio.a', one had to write

```
LIBRARIES = cpio
cpio_SOURCES = ...
```

Extra files to distribute must be listed in DIST_OTHER (the ancestor of EXTRA_DIST). Also extra directories that are to be distributed should appear in DIST_SUBDIRS, but the manual describes this as a temporary ugly hack (today extra directories should also be listed in EXTRA_DIST, and DIST_SUBDIRS is used for another purpose, see Section 7.2 [Conditional Subdirectories], page 49).

1995-11-26 Automake 0.21

In less time than it takes to cook a frozen pizza, Tom rewrites Automake using Perl. At this time Perl 5 is only one year old, and Perl 4.036 is in use at many sites. Supporting several Perl versions has been a source of problems through the whole history of Automake.

If you never used Perl 4, imagine Perl 5 without objects, without `my' variables (only dynamically scoped `local' variables), without function prototypes, with function calls that needs to be prefixed with `&', etc. Traces of this old style can still be found in today’s automake.

1995-11-28 Automake 0.22

1995-11-29 Automake 0.23

Bug fixes.

1995-12-08 Automake 0.24

1995-12-10 Automake 0.25

Releases are raining. 0.24 introduces the uniform naming scheme we use today, i.e., bin_PROGRAMS instead of PROGRAMS, noinst_LIBRARIES instead of LIBLIBRARIES, etc. (However EXTRA_PROGRAMS does not exist yet, AM_PROGRAMS is still in use; and TEXINFOS and MANS still have no directory prefixes.) Adding support for prefixes like that was one of the major ideas in automake; it has lasted pretty well.
AutoMake is renamed to Automake (Tom seems to recall it was François Pinard’s doing).

0.25 fixes a Perl 4 portability bug.

1995-12-18 Jim Meyering starts using Automake in GNU Textutils.
1995-12-31 François Pinard starts using Automake in GNU tar.
1996-01-03 Automake 0.26
1996-01-03 Automake 0.27

Of the many changes and suggestions sent by François Pinard and included in 0.26, perhaps the most important is the advice that to ease customization a user rule or variable definition should always override an Automake rule or definition.

Gordon Matzigkeit and Jim Meyering are two other early contributors that have been sending fixes.

0.27 fixes yet another Perl 4 portability bug.

1996-01-13 Automake 0.28

Automake starts scanning configure.in for LIBOBSJS support. This is an important step because until this version Automake only knew about the Makefile.am it processed. configure.in was Autoconf’s world and the link between Autoconf and Automake had to be done by the Makefile.am author. For instance, if config.h was generated by configure, it was the package maintainer’s responsibility to define the CONFIG_HEADER variable in each Makefile.am.

Succeeding releases will rely more and more on scanning configure.in to better automate the Autoconf integration.

0.28 also introduces the AUTOMAKE_OPTIONS variable and the --gnu and --gnits options, the latter being stricter.

1996-02-07 Automake 0.29

Thanks to configure.in scanning, CONFIG_HEADER is gone, and rebuild rules for configure-generated file are automatically output.

TEXINFOS and MANS converted to the uniform naming scheme.

1996-02-24 Automake 0.30

The test suite is born. It contains 9 tests. From now on test cases will be added pretty regularly (see Section 29.3 [Releases], page 162), and this proved to be really helpful later on.

EXTRA_PROGRAMS finally replaces AM_PROGRAMS.

All the third-party Autoconf macros, written mostly by François Pinard (and later Jim Meyering), are distributed in Automake’s hand-written aclocal.m4 file. Package maintainers are expected to extract the necessary macros from this file. (In previous versions you had to copy and paste them from the manual...)

1996-03-11 Automake 0.31

The test suite in 0.30 was run via a long check-local rule. Upon Ulrich Drepper’s suggestion, 0.31 makes it an Automake rule output whenever the TESTS variable is defined.
DIST_OTHER is renamed to EXTRA_DIST, and the check_prefix is introduced. The syntax is now the same as today.

1996-03-15 Gordon Matzigkeit starts writing libtool.

1996-04-27 Automake 0.32

-hook targets are introduced; an idea from Dieter Baron.

*.info files, which were output in the build directory are now built in the source directory, because they are distributed. It seems these files like to move back and forth as that will happen again in future versions.

1996-05-18 Automake 0.33

Gord Matzigkeit’s main two contributions:

- very preliminary libtool support
- the distcheck rule

Although they were very basic at this point, these are probably among the top features for Automake today.

Jim Meyering also provides the infamous jm_MAINTAINER_MODE, since then renamed to AM_MAINTAINER_MODE and abandoned by its author (see Section 28.2 [maintainer-mode], page 130).

1996-05-28 Automake 1.0

After only six months of heavy development, the automake script is 3134 lines long, plus 973 lines of Makefile fragments. The package has 30 pages of documentation, and 38 test cases. aclocal.m4 contains 4 macros.

From now on and until version 1.4, new releases will occur at a rate of about one a year. 1.1 did not exist, actually 1.1b to 1.1p have been the name of beta releases for 1.2. This is the first time Automake uses suffix letters to designate beta releases, a habit that lasts.

1996-10-10 Kevin Dalley packages Automake 1.0 for Debian GNU/Linux.

Between June and October, the Autoconf development is almost stalled. Roland McGrath has been working at the beginning of the year. David comes back in November to release 2.12, but he won’t touch Autoconf anymore after this year, and Autoconf then really stagnates. The desolate Autoconf ChangeLog for 1997 lists only 7 commits.

1997-02-28 automake@gnu.ai.mit.edu list alive

The mailing list is announced as follows:

I’ve created the "automake" mailing list. It is "automake@gnu.ai.mit.edu". Administrivia, as always, to automake-request@gnu.ai.mit.edu.

The charter of this list is discussion of automake, autoconf, and other configuration/portability tools (e.g., libtool). It is expected that discussion will range from pleas for help all the way up to patches.

This list is archived on the FSF machines. Offhand I don’t know if you can get the archive without an account there.
This list is open to anybody who wants to join. Tell all your friends!
-- Tom Tromey

Before that people were discussing Automake privately, on the Gnits mailing list (which is not public either), and less frequently on gnu.misc.discuss.

gnu.ai.mit.edu is now gnu.org, in case you never noticed. The archives of the early years of the automake@gnu.org list have been lost, so today it is almost impossible to find traces of discussions that occurred before 1999. This has been annoying more than once, as such discussions can be useful to understand the rationale behind a piece of uncommented code that was introduced back then.

1997-06-22 Automake 1.2

Automake developments continues, and more and more new Autoconf macros are required. Distributing them in aclocal.m4 and requiring people to browse this file to extract the relevant macros becomes uncomfortable. Ideally, some of them should be contributed to Autoconf so that they can be used directly, however Autoconf is currently inactive. Automake 1.2 consequently introduces aclocal (aclocal was actually started on 1996-07-28), a tool that automatically constructs an aclocal.m4 file from a repository of third-party macros. Because Autoconf has stalled, Automake also becomes a kind of repository for such third-party macros, even macros completely unrelated to Automake (for instance macros that fix broken Autoconf macros).

The 1.2 release contains 20 macros, including the AM_INIT_AUTOMAKE macro that simplifies the creation of configure.in.

Libtool is fully supported using *_LTLIBRARIES.

The missing script is introduced by François Pinard; it is meant to be a better solution than AM_MAINTAINER_MODE (see Section 28.2 [maintainer-mode], page 130).

Conditionals support was implemented by Ian Lance Taylor. At the time, Tom and Ian were working on an internal project at Cygnus. They were using ILU, which is pretty similar to CORBA. They wanted to integrate ILU into their build, which was all configure-based, and Ian thought that adding conditionals to automake was simpler than doing all the work in configure (which was the standard at the time). So this was actually funded by Cygnus.

This very useful but tricky feature will take a lot of time to stabilize. (At the time this text is written, there are still primaries that have not been updated to support conditional definitions in Automake 1.9.)

The automake script has almost doubled: 6089 lines of Perl, plus 1294 lines of Makefile fragments.

1997-07-08 Gordon Matzigkeit releases Libtool 1.0.
1998-04-05 Automake 1.3

This is a small advance compared to 1.2. It adds support for assembly, and preliminary support for Java.
Perl 5.004_04 is out, but fixes to support Perl 4 are still regularly submitted whenever Automake breaks it.

1998-09-06 sourceware.cygnus.com is on-line.
Sourceware was setup by Jason Molenda to host open source projects.

1998-09-19 Automake CVS repository moved to sourceware.cygnus.com
1998-10-26 sourceware.cygnus.com announces it hosts Automake:
Automake is now hosted on sourceware.cygnus.com. It has a publicly accessible CVS repository. This CVS repository is a copy of the one Tom was using on his machine, which in turn is based on a copy of the CVS repository of David MacKenzie. This is why we still have to full source history. (Automake was on Sourceware until 2007-10-29, when it moved to a git repository on savannah.gnu.org, but the Sourceware host had been renamed to sources.redhat.com.)
The oldest file in the administrative directory of the CVS repository that was created on Sourceware is dated 1998-09-19, while the announcement that automake and autoconf had joined sourceware was made on 1998-10-26. They were among the first projects to be hosted there.
The heedful reader will have noticed Automake was exactly 4 years old on 1998-09-19.

1999-01-14 Automake 1.4
This release adds support for Fortran 77 and for the include statement. Also, ‘+=’ assignments are introduced, but it is still quite easy to fool Automake when mixing this with conditionals.
These two releases, Automake 1.4 and Autoconf 2.13 make a duo that will be used together for years.
automake is 7228 lines, plus 1591 lines of Makefile fragment, 20 macros (some 1.3 macros were finally contributed back to Autoconf), 197 test cases, and 51 pages of documentation.

1999-03-27 The user-dep-branch is created on the CVS repository.
This implements a new dependency tracking scheme that should be able to handle automatic dependency tracking using any compiler (not just gcc) and any make (not just GNU make). In addition, the new scheme should be more reliable than the old one, as dependencies are generated on the end user’s machine. Alexandre Oliva creates depcomp for this purpose.
See Section 29.2 [Dependency Tracking Evolution], page 158, for more details about the evolution of automatic dependency tracking in Automake.

1999-11-21 The user-dep-branch is merged into the main trunk.
This was a huge problem since we also had patches going in on the trunk. The merge took a long time and was very painful.

2000-05-10
Since September 1999 and until 2003, Akim Demaille will be zealously revamping Autoconf.
I think the next release should be called "3.0". Let’s face it: you’ve basically rewritten autoconf. Every weekend there are 30 new patches. I don’t see how we could call this "2.15" with a straight face.

– Tom Tromey on autoconf@gnu.org

Actually Akim works like a submarine: he will pile up patches while he works off-line during the weekend, and flush them in batch when he resurfaces on Monday.

2001-01-24

On this Wednesday, Autoconf 2.49c, the last beta before Autoconf 2.50 is out, and Akim has to find something to do during his week-end :) 

2001-01-28

Akim sends a batch of 14 patches to automake@gnu.org.

Aiieee! I was dreading the day that the Demaillator turned his sights on automake... and now it has arrived! – Tom Tromey

It’s only the beginning: in two months he will send 192 patches. Then he would slow down so Tom can catch up and review all this. Initially Tom actually read all these patches, then he probably trustingly answered OK to most of them, and finally gave up and let Akim apply whatever he wanted. There was no way to keep up with that patch rate.

Anyway the patch below won’t apply since it predates Akim’s sourcequake; I have yet to figure where the relevant passage has been moved :) – Alexandre Duret-Lutz

All these patches were sent to and discussed on automake@gnu.org, so subscribed users were literally drowning in technical mails. Eventually, the automake-patches@gnu.org mailing list was created in May.

Year after year, Automake had drifted away from its initial design: construct Makefile.in by assembling various Makefile fragments. In 1.4, lots of Makefile rules are being emitted at various places in the automake script itself; this does not help ensuring a consistent treatment of these rules (for instance making sure that user-defined rules override Automake’s own rules). One of Akim’s goal was moving all these hard-coded rules to separate Makefile fragments, so the logic could be centralized in a Makefile fragment processor.

Another significant contribution of Akim is the interface with the “trace” feature of Autoconf. The way to scan configure.in at this time was to read the file and grep the various macro of interest to Automake. Doing so could break in many unexpected ways; automake could miss some definition (for instance ‘AC_SUBST([$1], [$2])’ where the arguments are known only when M4 is run), or conversely it could detect some macro that was not expanded (because it is called conditionally). In the CVS version of Autoconf, Akim had implemented the --trace option, which provides accurate information about where macros are actually called and with what arguments. Akim will equip Automake with a second configure.in scanner that uses this --trace interface. Since it was not sensible to drop the Autoconf 2.13 compatibility yet, this experimental
scanner was only used when an environment variable was set, the traditional
grep-scanner being still the default.

2001-04-25 Gary V. Vaughan releases Libtool 1.4
It has been more than two years since Automake 1.4, CVS Automake has
suffered lot’s of heavy changes and still is not ready for release. Libtool 1.4
had to be distributed with a patch against Automake 1.4.

2001-05-08 Automake 1.4-p1
2001-05-24 Automake 1.4-p2
Gary V. Vaughan, the principal Libtool maintainer, makes a “patch release” of
Automake:

The main purpose of this release is to have a stable automake which
is compatible with the latest stable libtool.

The release also contains obvious fixes for bugs in Automake 1.4, some of which
were reported almost monthly.

2001-05-21 Akim Demaille releases Autoconf 2.50
2001-06-07 Automake 1.4-p3
2001-06-10 Automake 1.4-p4
2001-07-15 Automake 1.4-p5
Gary continues his patch-release series. These also add support for some new
Autoconf 2.50 idioms. Essentially, Autoconf now advocates configure.ac over
configure.in, and it introduces a new syntax for AC_OUTPUTing files.

2001-08-23 Automake 1.5
A major and long-awaited release, that comes more than two years after 1.4.
It brings many changes, among which:

- The new dependency tracking scheme that uses depcomp. Aside from
  the improvement on the dependency tracking itself (see Section 29.2 [De-
  pendency Tracking Evolution], page 158), this also streamlines the use of
  automake-generated Makefile.ins as the Makefile.ins used during de-
  velopment are now the same as those used in distributions. Before that
  the Makefile.ins generated for maintainers required GNU make and GCC,
  they were different from the portable Makefile generated for distribution;
  this was causing some confusion.
- Support for per-target compilation flags.
- Support for reference to files in subdirectories in most Makefile.am vari-
  ables.
- Introduction of the dist_, nodist_, and nobase_ prefixes.
- Perl 4 support is finally dropped.

1.5 did break several packages that worked with 1.4. Enough so that Linux dis-
tributions could not easily install the new Automake version without breaking
many of the packages for which they had to run automake.

Some of these breakages were effectively bugs that would eventually be fixed in
the next release. However, a lot of damage was caused by some changes made
deliberately to render Automake stricter on some setup we did consider bogus.
For instance, `make distcheck` was improved to check that `make uninstall` did remove all the files `make install` installed, that `make distclean` did not omit some file, and that a VPATH build would work even if the source directory was read-only. Similarly, Automake now rejects multiple definitions of the same variable (because that would mix very badly with conditionals), and `+=` assignments with no previous definition. Because these changes all occurred suddenly after 1.4 had been established for more than two years, it hurt users.

To make matter worse, meanwhile Autoconf (now at version 2.52) was facing similar troubles, for similar reasons.

2002-03-05 Automake 1.6

This release introduced versioned installation (see Chapter 26 [API Versioning], page 126). This was mainly pushed by Havoc Pennington, taking the GNOME source tree as motive: due to incompatibilities between the autotools it’s impossible for the GNOME packages to switch to Autoconf 2.53 and Automake 1.5 all at once, so they are currently stuck with Autoconf 2.13 and Automake 1.4.

The idea was to call this version `automake-1.6`, call all its bug-fix versions identically, and switch to `automake-1.7` for the next release that adds new features or changes some rules. This scheme implies maintaining a bug-fix branch in addition to the development trunk, which means more work from the maintainer, but providing regular bug-fix releases proved to be really worthwhile.

Like 1.5, 1.6 also introduced a bunch of incompatibilities, intentional or not. Perhaps the more annoying was the dependence on the newly released Autoconf 2.53. Autoconf seemed to have stabilized enough since its explosive 2.50 release and included changes required to fix some bugs in Automake. In order to upgrade to Automake 1.6, people now had to upgrade Autoconf too; for some packages it was no picnic.

While versioned installation helped people to upgrade, it also unfortunately allowed people not to upgrade. At the time of writing, some Linux distributions are shipping packages for Automake 1.4, 1.5, 1.6, 1.7, 1.8, and 1.9. Most of these still install 1.4 by default. Some distribution also call 1.4 the “stable” version, and present “1.9” as the development version; this does not really makes sense since 1.9 is way more solid than 1.4. All this does not help the newcomer.

2002-04-11 Automake 1.6.1

1.6, and the upcoming 1.4-p6 release were the last release by Tom. This one and those following will be handled by Alexandre Duret-Lutz. Tom is still around, and will be there until about 1.7, but his interest into Automake is drifting away towards projects like gcj.

Alexandre has been using Automake since 2000, and started to contribute mostly on Akim’s incitement (Akim and Alexandre have been working in the same room from 1999 to 2002). In 2001 and 2002 he had a lot of free time to enjoy hacking Automake.
Chapter 29: History of Automake

2002-06-14 Automake 1.6.2
2002-07-28 Automake 1.6.3
2002-07-28 Automake 1.4-p6
  Two releases on the same day. 1.6.3 is a bug-fix release.
  Tom Tromey backported the versioned installation mechanism on the 1.4
  branch, so that Automake 1.6.x and Automake 1.4-p6 could be installed side
  by side. Another request from the GNOME folks.

2002-09-25 Automake 1.7
  This release switches to the new configure.ac scanner Akim was experiment-
  ing in 1.5.

2002-10-16 Automake 1.7.1
2002-12-06 Automake 1.7.2
2003-02-20 Automake 1.7.3
2003-04-23 Automake 1.7.4
2003-05-18 Automake 1.7.5
2003-07-10 Automake 1.7.6
2003-09-07 Automake 1.7.7
2003-10-07 Automake 1.7.8
  Many bug-fix releases. 1.7 lasted because the development version (upcoming
  1.8) was suffering some major internal revamping.

2003-10-26 Automake on screen
  Episode 49, ‘Repercussions’, in the third season of the ‘Alias’ TV show is first
  aired.
  Marshall, one of the characters, is working on a computer virus that he has
  to modify before it gets into the wrong hands or something like that. The
  screenshots you see do not show any program code, they show a Makefile.in
  generated by automake...

2003-11-09 Automake 1.7.9
2003-12-10 Automake 1.8
  The most striking update is probably that of aclocal.
  aclocal now uses m4_include in the produced aclocal.m4 when the included
  macros are already distributed with the package (an idiom used in many pack-
  ages), which reduces code duplication. Many people liked that, but in fact this
  change was really introduced to fix a bug in rebuild rules: Makefile.in must
  be rebuilt whenever a dependency of configure changes, but all the m4 files
  included in aclocal.m4 are unknown from automake. Now automake can
  just trace the m4_includes to discover the dependencies.
  aclocal also starts using the --trace Autoconf option in order to discover used
  macros more accurately. This will turn out to be very tricky (later releases will
  improve this) as people had devised many ways to cope with the limitation of
  previous aclocal versions, notably using handwritten m4_includes: aclocal
  must make sure not to redefine a rule that is already included by such statement.
  Automake also has seen its guts rewritten. Although this rewriting took a lot
  of efforts, it is only apparent to the users in that some constructions previously
29.2 Dependency Tracking in Automake

Over the years Automake has deployed three different dependency tracking methods. Each method, including the current one, has had flaws of various sorts. Here we lay out the different dependency tracking methods, their flaws, and their fixes. We conclude with recommendations for tool writers, and by indicating future directions for dependency tracking work in Automake.

29.2.1 First Take on Dependency Tracking

Description

Our first attempt at automatic dependency tracking was based on the method recommended by GNU make. (see Section “Generating Prerequisites Automatically” in The GNU make Manual)

This version worked by precomputing dependencies ahead of time. For each source file, it had a special .P file that held the dependencies. There was a rule to generate a .P file by invoking the compiler appropriately. All such .P files were included by the Makefile, thus implicitly becoming dependencies of Ma.kehfile.

Bugs

This approach had several critical bugs.

- The code to generate the .P file relied on gcc. (A limitation, not technically a bug.)
• The dependency tracking mechanism itself relied on GNU make. (A limitation, not technically a bug.)

• Because each .P file was a dependency of Makefile, this meant that dependency tracking was done eagerly by make. For instance, make clean would cause all the dependency files to be updated, and then immediately removed. This eagerness also caused problems with some configurations; if a certain source file could not be compiled on a given architecture for some reason, dependency tracking would fail, aborting the entire build.

• As dependency tracking was done as a pre-pass, compile times were doubled—the compiler had to be run twice per source file.

• make dist re-ran automake to generate a Makefile that did not have automatic dependency tracking (and that was thus portable to any version of make). In order to do this portably, Automake had to scan the dependency files and remove any reference that was to a source file not in the distribution. This process was error-prone. Also, if make dist was run in an environment where some object file had a dependency on a source file that was only conditionally created, Automake would generate a Makefile that referred to a file that might not appear in the end user’s build. A special, hacky mechanism was required to work around this.

Historical Note

The code generated by Automake is often inspired by the Makefile style of a particular author. In the case of the first implementation of dependency tracking, I believe the impetus and inspiration was Jim Meyering. (I could be mistaken. If you know otherwise feel free to correct me.)

29.2.2 Dependencies As Side Effects

Description

The next refinement of Automake’s automatic dependency tracking scheme was to implement dependencies as side effects of the compilation. This was aimed at solving the most commonly reported problems with the first approach. In particular we were most concerned with eliminating the weird rebuilding effect associated with make clean.

In this approach, the .P files were included using the -include command, which let us create these files lazily. This avoided the make clean problem.

We only computed dependencies when a file was actually compiled. This avoided the performance penalty associated with scanning each file twice. It also let us avoid the other problems associated with the first, eager, implementation. For instance, dependencies would never be generated for a source file that was not compilable on a given architecture (because it in fact would never be compiled).

Bugs

• This approach also relied on the existence of gcc and GNU make. (A limitation, not technically a bug.)

• Dependency tracking was still done by the developer, so the problems from the first implementation relating to massaging of dependencies by make dist were still in effect.
• This implementation suffered from the “deleted header file” problem. Suppose a lazily-created .P file includes a dependency on a given header file, like this:

\[\text{maude.o: maude.c something.h}\]

Now suppose that you remove \textit{something.h} and update \textit{maude.c} so that this include is no longer needed. If you run \texttt{make}, you will get an error because there is no way to create \textit{something.h}.

We fixed this problem in a later release by further massaging the output of \texttt{gcc} to include a dummy dependency for each header file.

29.2.3 Dependencies for the User

Description

The bugs associated with \texttt{make dist}, over time, became a real problem. Packages using Automake were being built on a large number of platforms, and were becoming increasingly complex. Broken dependencies were distributed in “portable” \texttt{Makefile.in}s, leading to user complaints. Also, the requirement for \texttt{gcc} and GNU \texttt{make} was a constant source of bug reports. The next implementation of dependency tracking aimed to remove these problems.

We realized that the only truly reliable way to automatically track dependencies was to do it when the package itself was built. This meant discovering a method portable to any version of make and any compiler. Also, we wanted to preserve what we saw as the best point of the second implementation: dependency computation as a side effect of compilation.

In the end we found that most modern make implementations support some form of include directive. Also, we wrote a wrapper script that let us abstract away differences between dependency tracking methods for compilers. For instance, some compilers cannot generate dependencies as a side effect of compilation. In this case we simply have the script run the compiler twice. Currently our wrapper script \texttt{(depcomp)} knows about twelve different compilers (including a "compiler" that simply invokes \texttt{makedepend} and then the real compiler, which is assumed to be a standard Unix-like C compiler with no way to do dependency tracking).

Bugs

• Running a wrapper script for each compilation slows down the build.
• Many users don’t really care about precise dependencies.
• This implementation, like every other automatic dependency tracking scheme in common use today (indeed, every one we’ve ever heard of), suffers from the “duplicated new header” bug.

This bug occurs because dependency tracking tools, such as the compiler, only generate dependencies on the successful opening of a file, and not on every probe.

Suppose for instance that the compiler searches three directories for a given header, and that the header is found in the third directory. If the programmer erroneously adds a header file with the same name to the first directory, then a clean rebuild from scratch could fail (suppose the new header file is buggy), whereas an incremental rebuild will succeed.
What has happened here is that people have a misunderstanding of what a dependency is. Tool writers think a dependency encodes information about which files were read by the compiler. However, a dependency must actually encode information about what the compiler tried to do.

This problem is not serious in practice. Programmers typically do not use the same name for a header file twice in a given project. (At least, not in C or C++. This problem may be more troublesome in Java.) This problem is easy to fix, by modifying dependency generators to record every probe, instead of every successful open.

- Since Automake generates dependencies as a side effect of compilation, there is a bootstrapping problem when header files are generated by running a program. The problem is that, the first time the build is done, there is no way by default to know that the headers are required, so make might try to run a compilation for which the headers have not yet been built.

This was also a problem in the previous dependency tracking implementation.

The current fix is to use `BUILT_SOURCES` to list built headers (see Section 9.4 [Sources], page 85). This causes them to be built before any other build rules are run. This is unsatisfactory as a general solution, however in practice it seems sufficient for most actual programs.

This code is used since Automake 1.5.

In GCC 3.0, we managed to convince the maintainers to add special command-line options to help Automake more efficiently do its job. We hoped this would let us avoid the use of a wrapper script when Automake’s automatic dependency tracking was used with `gcc`.

Unfortunately, this code doesn’t quite do what we want. In particular, it removes the dependency file if the compilation fails; we’d prefer that it instead only touch the file in any way if the compilation succeeds.

Nevertheless, since Automake 1.7, when a recent `gcc` is detected at `configure` time, we inline the dependency-generation code and do not use the `depcomp` wrapper script. This makes compilations faster for those using this compiler (probably our primary user base). The counterpart is that because we have to encode two compilation rules in `Makefile` (with or without `depcomp`), the produced `Makefiles` are larger.

### 29.2.4 Techniques for Computing Dependencies

There are actually several ways for a build tool like Automake to cause tools to generate dependencies.

**makedepend**

This was a commonly-used method in the past. The idea is to run a special program over the source and have it generate dependency information. Traditional implementations of `makedepend` are not completely precise; ordinarily they were conservative and discovered too many dependencies.

The tool

An obvious way to generate dependencies is to simply write the tool so that it can generate the information needed by the build tool. This is also the most portable method. Many compilers have an option to generate dependencies. Unfortunately, not all tools provide such an option.
The file system

It is possible to write a special file system that tracks opens, reads, writes, etc, and then feed this information back to the build tool. clearmake does this. This is a very powerful technique, as it doesn't require cooperation from the tool. Unfortunately it is also very difficult to implement and also not practical in the general case.

LD_PRELOAD

Rather than use the file system, one could write a special library to intercept open and other syscalls. This technique is also quite powerful, but unfortunately it is not portable enough for use in automake.

29.2.5 Recommendations for Tool Writers

We think that every compilation tool ought to be able to generate dependencies as a side effect of compilation. Furthermore, at least while make-based tools are nearly universally in use (at least in the free software community), the tool itself should generate dummy dependencies for header files, to avoid the deleted header file bug. Finally, the tool should generate a dependency for each probe, instead of each successful file open, in order to avoid the duplicated new header bug.

29.2.6 Future Directions for Dependencies

Currently, only languages and compilers understood by Automake can have dependency tracking enabled. We would like to see if it is practical (and worthwhile) to let this support be extended by the user to languages unknown to Automake.

29.3 Release Statistics

The following table (inspired by 'perlhist(1)') quantifies the evolution of Automake using these metrics:

Appendix A Copying This Manual

A.1 GNU Free Documentation License

Version 1.3, 3 November 2008

http://fsf.org/

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

0. PREAMBLE

The purpose of this License is to make a manual, textbook, or other functional and useful document free in the sense of freedom: to assure everyone the effective freedom to copy and redistribute it, with or without modifying it, either commercially or non-commercially. Secondarily, this License preserves for the author and publisher a way to get credit for their work, while not being considered responsible for modifications made by others.

This License is a kind of “copyleft”, which means that derivative works of the document must themselves be free in the same sense. It complements the GNU General Public License, which is a copyleft license designed for free software.

We have designed this License in order to use it for manuals for free software, because free software needs free documentation: a free program should come with manuals providing the same freedoms that the software does. But this License is not limited to software manuals; it can be used for any textual work, regardless of subject matter or whether it is published as a printed book. We recommend this License principally for works whose purpose is instruction or reference.

1. APPLICABILITY AND DEFINITIONS

This License applies to any manual or other work, in any medium, that contains a notice placed by the copyright holder saying it can be distributed under the terms of this License. Such a notice grants a world-wide, royalty-free license, unlimited in duration, to use that work under the conditions stated herein. The “Document”, below, refers to any such manual or work. Any member of the public is a licensee, and is addressed as “you”. You accept the license if you copy, modify or distribute the work in a way requiring permission under copyright law.

A “Modified Version” of the Document means any work containing the Document or a portion of it, either copied verbatim, or with modifications and/or translated into another language.

A “Secondary Section” is a named appendix or a front-matter section of the Document that deals exclusively with the relationship of the publishers or authors of the Document to the Document’s overall subject (or to related matters) and contains nothing that could fall directly within that overall subject. (Thus, if the Document is in part a textbook of mathematics, a Secondary Section may not explain any mathematics.) The relationship could be a matter of historical connection with the subject or with related matters, or of legal, commercial, philosophical, ethical or political position regarding them.
The “Invariant Sections” are certain Secondary Sections whose titles are designated, as being those of Invariant Sections, in the notice that says that the Document is released under this License. If a section does not fit the above definition of Secondary then it is not allowed to be designated as Invariant. The Document may contain zero Invariant Sections. If the Document does not identify any Invariant Sections then there are none.

The “Cover Texts” are certain short passages of text that are listed, as Front-Cover Texts or Back-Cover Texts, in the notice that says that the Document is released under this License. A Front-Cover Text may be at most 5 words, and a Back-Cover Text may be at most 25 words.

A “Transparent” copy of the Document means a machine-readable copy, represented in a format whose specification is available to the general public, that is suitable for revising the document straightforwardly with generic text editors or (for images composed of pixels) generic paint programs or (for drawings) some widely available drawing editor, and that is suitable for input to text formatters or for automatic translation to a variety of formats suitable for input to text formatters. A copy made in an otherwise Transparent file format whose markup, or absence of markup, has been arranged to thwart or discourage subsequent modification by readers is not Transparent. An image format is not Transparent if used for any substantial amount of text. A copy that is not “Transparent” is called “Opaque”.

Examples of suitable formats for Transparent copies include plain ASCII without markup, Texinfo input format, \LaTeX \textsf{X} input format, SGML or XML using a publicly available DTD, and standard-conforming simple HTML, PostScript or PDF designed for human modification. Examples of transparent image formats include PNG, XCF and JPG. Opaque formats include proprietary formats that can be read and edited only by proprietary word processors, SGML or XML for which the DTD and/or processing tools are not generally available, and the machine-generated HTML, PostScript or PDF produced by some word processors for output purposes only.

The “Title Page” means, for a printed book, the title page itself, plus such following pages as are needed to hold, legibly, the material this License requires to appear in the title page. For works in formats which do not have any title page as such, “Title Page” means the text near the most prominent appearance of the work’s title, preceding the beginning of the body of the text.

The “publisher” means any person or entity that distributes copies of the Document to the public.

A section “Entitled XYZ” means a named subunit of the Document whose title either is precisely XYZ or contains XYZ in parentheses following text that translates XYZ in another language. (Here XYZ stands for a specific section name mentioned below, such as “Acknowledgements”, “Dedications”, “Endorsements”, or “History”.) To “Preserve the Title” of such a section when you modify the Document means that it remains a section “Entitled XYZ” according to this definition.

The Document may include Warranty Disclaimers next to the notice which states that this License applies to the Document. These Warranty Disclaimers are considered to be included by reference in this License, but only as regards disclaiming warranties: any other implication that these Warranty Disclaimers may have is void and has no effect on the meaning of this License.
2. VERBATIM COPYING

You may copy and distribute the Document in any medium, either commercially or noncommercially, provided that this License, the copyright notices, and the license notice saying this License applies to the Document are reproduced in all copies, and that you add no other conditions whatsoever to those of this License. You may not use technical measures to obstruct or control the reading or further copying of the copies you make or distribute. However, you may accept compensation in exchange for copies. If you distribute a large enough number of copies you must also follow the conditions in section 3.

You may also lend copies, under the same conditions stated above, and you may publicly display copies.

3. COPYING IN QUANTITY

If you publish printed copies (or copies in media that commonly have printed covers) of the Document, numbering more than 100, and the Document’s license notice requires Cover Texts, you must enclose the copies in covers that carry, clearly and legibly, all these Cover Texts: Front-Cover Texts on the front cover, and Back-Cover Texts on the back cover. Both covers must also clearly and legibly identify you as the publisher of these copies. The front cover must present the full title with all words of the title equally prominent and visible. You may add other material on the covers in addition. Copying with changes limited to the covers, as long as they preserve the title of the Document and satisfy these conditions, can be treated as verbatim copying in other respects.

If the required texts for either cover are too voluminous to fit legibly, you should put the first ones listed (as many as fit reasonably) on the actual cover, and continue the rest onto adjacent pages.

If you publish or distribute Opaque copies of the Document numbering more than 100, you must either include a machine-readable Transparent copy along with each Opaque copy, or state in or with each Opaque copy a computer-network location from which the general network-using public has access to download using public-standard network protocols a complete Transparent copy of the Document, free of added material. If you use the latter option, you must take reasonably prudent steps, when you begin distribution of Opaque copies in quantity, to ensure that this Transparent copy will remain thus accessible at the stated location until at least one year after the last time you distribute an Opaque copy (directly or through your agents or retailers) of that edition to the public.

It is requested, but not required, that you contact the authors of the Document well before redistributing any large number of copies, to give them a chance to provide you with an updated version of the Document.

4. MODIFICATIONS

You may copy and distribute a Modified Version of the Document under the conditions of sections 2 and 3 above, provided that you release the Modified Version under precisely this License, with the Modified Version filling the role of the Document, thus licensing distribution and modification of the Modified Version to whoever possesses a copy of it. In addition, you must do these things in the Modified Version:
A. Use in the Title Page (and on the covers, if any) a title distinct from that of the Document, and from those of previous versions (which should, if there were any, be listed in the History section of the Document). You may use the same title as a previous version if the original publisher of that version gives permission.

B. List on the Title Page, as authors, one or more persons or entities responsible for authorship of the modifications in the Modified Version, together with at least five of the principal authors of the Document (all of its principal authors, if it has fewer than five), unless they release you from this requirement.

C. State on the Title page the name of the publisher of the Modified Version, as the publisher.

D. Preserve all the copyright notices of the Document.

E. Add an appropriate copyright notice for your modifications adjacent to the other copyright notices.

F. Include, immediately after the copyright notices, a license notice giving the public permission to use the Modified Version under the terms of this License, in the form shown in the Addendum below.

G. Preserve in that license notice the full lists of Invariant Sections and required Cover Texts given in the Document’s license notice.

H. Include an unaltered copy of this License.

I. Preserve the section Entitled “History”, Preserve its Title, and add to it an item stating at least the title, year, new authors, and publisher of the Modified Version as given on the Title Page. If there is no section Entitled “History” in the Document, create one stating the title, year, authors, and publisher of the Document as given on its Title Page, then add an item describing the Modified Version as stated in the previous sentence.

J. Preserve the network location, if any, given in the Document for public access to a Transparent copy of the Document, and likewise the network locations given in the Document for previous versions it was based on. These may be placed in the “History” section. You may omit a network location for a work that was published at least four years before the Document itself, or if the original publisher of the version it refers to gives permission.

K. For any section Entitled “Acknowledgements” or “Dedications”, Preserve the Title of the section, and preserve in the section all the substance and tone of each of the contributor acknowledgements and/or dedications given therein.

L. Preserve all the Invariant Sections of the Document, unaltered in their text and in their titles. Section numbers or the equivalent are not considered part of the section titles.

M. Delete any section Entitled “Endorsements”. Such a section may not be included in the Modified Version.

N. Do not retitle any existing section to be Entitled “Endorsements” or to conflict in title with any Invariant Section.

O. Preserve any Warranty Disclaimers.

If the Modified Version includes new front-matter sections or appendices that qualify as Secondary Sections and contain no material copied from the Document, you may at
your option designate some or all of these sections as invariant. To do this, add their
titles to the list of Invariant Sections in the Modified Version’s license notice. These
titles must be distinct from any other section titles.
You may add a section Entitled “Endorsements”, provided it contains nothing but
endorsements of your Modified Version by various parties—for example, statements of
peer review or that the text has been approved by an organization as the authoritative
definition of a standard.
You may add a passage of up to five words as a Front-Cover Text, and a passage of up
to 25 words as a Back-Cover Text, to the end of the list of Cover Texts in the Modified
Version. Only one passage of Front-Cover Text and one of Back-Cover Text may be
added by (or through arrangements made by) any one entity. If the Document already
includes a cover text for the same cover, previously added by you or by arrangement
made by the same entity you are acting on behalf of, you may not add another; but
you may replace the old one, on explicit permission from the previous publisher that
added the old one.
The author(s) and publisher(s) of the Document do not by this License give permission
to use their names for publicity for or to assert or imply endorsement of any Modified
Version.
5. COMBINING DOCUMENTS
You may combine the Document with other documents released under this License,
under the terms defined in section 4 above for modified versions, provided that you
include in the combination all of the Invariant Sections of all of the original documents,
unmodified, and list them all as Invariant Sections of your combined work in its license
notice, and that you preserve all their Warranty Disclaimers.
The combined work need only contain one copy of this License, and multiple identical
Invariant Sections may be replaced with a single copy. If there are multiple Invariant
Sections with the same name but different contents, make the title of each such section
unique by adding at the end of it, in parentheses, the name of the original author or
publisher of that section if known, or else a unique number. Make the same adjustment
to the section titles in the list of Invariant Sections in the license notice of the combined
work.
In the combination, you must combine any sections Entitled “History” in the vari-
ous original documents, forming one section Entitled “History”; likewise combine any
sections Entitled “Acknowledgements”, and any sections Entitled “Dedications”. You
must delete all sections Entitled “Endorsements.”
6. COLLECTIONS OF DOCUMENTS
You may make a collection consisting of the Document and other documents released
under this License, and replace the individual copies of this License in the various
documents with a single copy that is included in the collection, provided that you
follow the rules of this License for verbatim copying of each of the documents in all
other respects.
You may extract a single document from such a collection, and distribute it individu-
ally under this License, provided you insert a copy of this License into the extracted
document, and follow this License in all other respects regarding verbatim copying of
that document.
7. AGGREGATION WITH INDEPENDENT WORKS

A compilation of the Document or its derivatives with other separate and independent
documents or works, in or on a volume of a storage or distribution medium, is called
an “aggregate” if the copyright resulting from the compilation is not used to limit the
legal rights of the compilation’s users beyond what the individual works permit. When
the Document is included in an aggregate, this License does not apply to the other
works in the aggregate which are not themselves derivative works of the Document.

If the Cover Text requirement of section 3 is applicable to these copies of the Document,
then if the Document is less than one half of the entire aggregate, the Document’s Cover
Texts may be placed on covers that bracket the Document within the aggregate, or the
electronic equivalent of covers if the Document is in electronic form. Otherwise they
must appear on printed covers that bracket the whole aggregate.

8. TRANSLATION

Translation is considered a kind of modification, so you may distribute translations
of the Document under the terms of section 4. Replacing Invariant Sections with
translations requires special permission from their copyright holders, but you may
include translations of some or all Invariant Sections in addition to the original versions
of these Invariant Sections. You may include a translation of this License, and all the
license notices in the Document, and any Warranty Disclaimers, provided that you
also include the original English version of this License and the original versions of
those notices and disclaimers. In case of a disagreement between the translation and
the original version of this License or a notice or disclaimer, the original version will
prevail.

If a section in the Document is Entitled “Acknowledgements”, “Dedications”, or “His-
tory”, the requirement (section 4) to Preserve its Title (section 1) will typically require
changing the actual title.

9. TERMINATION

You may not copy, modify, sublicense, or distribute the Document except as expressly
provided under this License. Any attempt otherwise to copy, modify, sublicense, or
distribute it is void, and will automatically terminate your rights under this License.

However, if you cease all violation of this License, then your license from a particular
copyright holder is reinstated (a) provisionally, unless and until the copyright holder
explicitly and finally terminates your license, and (b) permanently, if the copyright
holder fails to notify you of the violation by some reasonable means prior to 60 days
after the cessation.

Moreover, your license from a particular copyright holder is reinstated permanently if
the copyright holder notifies you of the violation by some reasonable means, this is the
first time you have received notice of violation of this License (for any work) from that
copyright holder, and you cure the violation prior to 30 days after your receipt of the
notice.

Termination of your rights under this section does not terminate the licenses of parties
who have received copies or rights from you under this License. If your rights have
been terminated and not permanently reinstated, receipt of a copy of some or all of the
same material does not give you any rights to use it.
10. FUTURE REVISIONS OF THIS LICENSE

The Free Software Foundation may publish new, revised versions of the GNU Free Documentation License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns. See http://www.gnu.org/copyleft/.

Each version of the License is given a distinguishing version number. If the Document specifies that a particular numbered version of this License “or any later version” applies to it, you have the option of following the terms and conditions either of that specified version or of any later version that has been published (not as a draft) by the Free Software Foundation. If the Document does not specify a version number of this License, you may choose any version ever published (not as a draft) by the Free Software Foundation. If the Document specifies that a proxy can decide which future versions of this License can be used, that proxy’s public statement of acceptance of a version permanently authorizes you to choose that version for the Document.

11. RELICENSING

“Massive Multiauthor Collaboration Site” (or “MMC Site”) means any World Wide Web server that publishes copyrightable works and also provides prominent facilities for anybody to edit those works. A public wiki that anybody can edit is an example of such a server. A “Massive Multiauthor Collaboration” (or “MMC”) contained in the site means any set of copyrightable works thus published on the MMC site.

“CC-BY-SA” means the Creative Commons Attribution-Share Alike 3.0 license published by Creative Commons Corporation, a not-for-profit corporation with a principal place of business in San Francisco, California, as well as future copyleft versions of that license published by that same organization.

“Incorporate” means to publish or republish a Document, in whole or in part, as part of another Document.

An MMC is “eligible for relicensing” if it is licensed under this License, and if all works that were first published under this License somewhere other than this MMC, and subsequently incorporated in whole or in part into the MMC, (1) had no cover texts or invariant sections, and (2) were thus incorporated prior to November 1, 2008.

The operator of an MMC Site may republish an MMC contained in the site under CC-BY-SA on the same site at any time before August 1, 2009, provided the MMC is eligible for relicensing.
ADDENDUM: How to use this License for your documents

To use this License in a document you have written, include a copy of the License in the
document and put the following copyright and license notices just after the title page:

Copyright (C) year your name.
Permission is granted to copy, distribute and/or modify this document
under the terms of the GNU Free Documentation License, Version 1.3
or any later version published by the Free Software Foundation;
with no Invariant Sections, no Front-Cover Texts, and no Back-Cover
Texts. A copy of the license is included in the section entitled ‘‘GNU
Free Documentation License’’.

If you have Invariant Sections, Front-Cover Texts and Back-Cover Texts, replace the
“with...Texts.” line with this:

with the Invariant Sections being list their titles, with
the Front-Cover Texts being list, and with the Back-Cover Texts
being list.

If you have Invariant Sections without Cover Texts, or some other combination of the
three, merge those two alternatives to suit the situation.

If your document contains nontrivial examples of program code, we recommend releasing
these examples in parallel under your choice of free software license, such as the GNU
General Public License, to permit their use in free software.
