Chapter 1

GNU Internationalized Domain Name Library

1.1 Introduction

GNU Libidn is an implementation of the Stringprep, Punycode and IDNA specifications defined by the IETF Internationalized Domain Names (IDN) working group, used for internationalized domain names. The package is available under the GNU Lesser General Public License.

The library contains a generic Stringprep implementation that does Unicode 3.2 NFKC normalization, mapping and prohibition of characters, and bidirectional character handling. Profiles for Nameprep, iSCSI, SASL and XMPP are included. Punycode and ASCII Compatible Encoding (ACE) via IDNA are supported. A mechanism to define Top-Level Domain (TLD) specific validation tables, and to compare strings against those tables, is included. Default tables for some TLDs are also included.

The Stringprep API consists of two main functions, one for converting data from the system's native representation into UTF-8, and one function to perform the Stringprep processing. Adding a new Stringprep profile for your application within the API is straightforward. The Punycode API consists of one encoding function and one decoding function. The IDNA API consists of the ToASCII and ToUnicode functions, as well as an high-level interface for converting entire domain names to and from the ACE encoded form. The TLD API consists of one set of functions to extract the TLD name from a domain string, one set of functions to locate the proper TLD table to use based on the TLD name, and core functions to validate a string against a TLD table, and some utility wrappers to perform all the steps in one call.

The library is used by, e.g., GNU SASL and Shishi to process user names and passwords. Libidn can be built into GNU Libc to enable a new system-wide `getaddrinfo()` flag for IDN processing.

Libidn is developed for the GNU/Linux system, but runs on over 20 Unix platforms (including Solaris, IRIX, AIX, and Tru64) and Windows. Libidn is written in C and (parts of) the API is accessible from C, C++, Emacs Lisp, Python and Java.

Chapter 4

Data Structure Documentation

4.1 decomposition Struct Reference

```
#include <gunidecomp.h>
```

Data Fields

- `gunichar ch`
- `quint16 canon_offset`
- `quint16 compat_offset`

4.1.1 Detailed Description

Definition at line 1826 of file gunidecomp.h.

4.1.2 Field Documentation

4.1.2.1 canon_offset

```
quint16 decomposition::canon_offset
```

Definition at line 1829 of file gunidecomp.h.

4.1.2.2 ch

```
gunichar decomposition::ch
```

Definition at line 1828 of file gunidecomp.h.

4.1.2.3 compat_offset

`uint16 decomposition::compat_offset`

Definition at line 1830 of file gunidecomp.h.

The documentation for this struct was generated from the following file:

- [gunidecomp.h](#)

4.2 Pr29 Struct Reference

Data Fields

- `const uint32_t * first`
- `const uint32_t * last`

4.2.1 Detailed Description

Definition at line 1172 of file pr29.c.

4.2.2 Field Documentation

4.2.2.1 first

`const uint32_t* Pr29::first`

Definition at line 1174 of file pr29.c.

4.2.2.2 last

`const uint32_t* Pr29::last`

Definition at line 1175 of file pr29.c.

The documentation for this struct was generated from the following file:

- [pr29.c](#)

4.3 Stringprep_profiles Struct Reference

`#include <stringprep.h>`

Data Fields

- `const char * name`
- `const Stringprep_profile * tables`

4.3.1 Detailed Description

[Stringprep_profiles](#):

Parameters

<i>name</i>	name of stringprep profile.
<i>tables</i>	zero-terminated array of Stringprep_profile elements.

Element structure

Definition at line 169 of file stringprep.h.

4.3.2 Field Documentation

4.3.2.1 name

```
const char* Stringprep_profiles::name
```

Definition at line 171 of file stringprep.h.

4.3.2.2 tables

```
const Stringprep_profile* Stringprep_profiles::tables
```

Definition at line 172 of file stringprep.h.

The documentation for this struct was generated from the following file:

- [stringprep.h](#)

4.4 Stringprep_table Struct Reference

```
#include <stringprep.h>
```

Data Fields

- [Stringprep_profile_steps](#) operation
- [Stringprep_profile_flags](#) flags
- const [Stringprep_table_element](#) * table
- [size_t](#) table_size

4.4.1 Detailed Description

[Stringprep_table](#):

Parameters

<i>operation</i>	a <code>Stringprep_profile_steps</code> value
<i>flags</i>	a <code>Stringprep_profile_flags</code> value
<i>table</i>	zero-terminated array of <code>Stringprep_table_element</code> elements.
<i>table_size</i>	size of @table, to speed up searching.

Stringprep profile table.

Definition at line 148 of file stringprep.h.

4.4.2 Field Documentation

4.4.2.1 flags

`Stringprep_profile_flags` `Stringprep_table::flags`

Definition at line 151 of file stringprep.h.

4.4.2.2 operation

`Stringprep_profile_steps` `Stringprep_table::operation`

Definition at line 150 of file stringprep.h.

4.4.2.3 table

`const Stringprep_table_element*` `Stringprep_table::table`

Definition at line 152 of file stringprep.h.

4.4.2.4 table_size

`size_t` `Stringprep_table::table_size`

Definition at line 153 of file stringprep.h.

The documentation for this struct was generated from the following file:

- [stringprep.h](#)

4.5 Stringprep_table_element Struct Reference

```
#include <stringprep.h>
```

Data Fields

- `uint32_t start`
- `uint32_t end`
- `uint32_t map [STRINGPREP_MAX_MAP_CHARS]`

4.5.1 Detailed Description

`Stringprep_table_element`:

Parameters

<code>start</code>	starting codepoint.
<code>end</code>	ending codepoint, 0 if only one character.
<code>map</code>	codepoints to map @start into, NULL if end is not 0.

Stringprep profile table element.

Definition at line 131 of file stringprep.h.

4.5.2 Field Documentation

4.5.2.1 `end`

```
uint32_t Stringprep_table_element::end
```

Definition at line 134 of file stringprep.h.

4.5.2.2 `map`

```
uint32_t Stringprep_table_element::map[STRINGPREP_MAX_MAP_CHARS]
```

Definition at line 135 of file stringprep.h.

4.5.2.3 start

```
uint32_t Stringprep_table_element::start
```

Definition at line 133 of file stringprep.h.

The documentation for this struct was generated from the following file:

- [stringprep.h](#)

4.6 Tld_table Struct Reference

```
#include <tld.h>
```

Data Fields

- const char * [name](#)
- const char * [version](#)
- size_t [nvalid](#)
- const [Tld_table_element](#) * [valid](#)

4.6.1 Detailed Description

[Tld_table](#):

Parameters

name	TLD name, e.g., "no".
version	Version string from TLD file.
nvalid	Number of entries in data.
valid	Sorted array (of size @nvalid) of valid code points.

List valid code points in a TLD.

Definition at line 94 of file tld.h.

4.6.2 Field Documentation

4.6.2.1 name

```
const char* Tld_table::name
```

Definition at line 96 of file tld.h.

4.6.2.2 nvalid

```
size_t TId_table::nvalid
```

Definition at line 98 of file tld.h.

4.6.2.3 valid

```
const TId_table_element* TId_table::valid
```

Definition at line 99 of file tld.h.

4.6.2.4 version

```
const char* TId_table::version
```

Definition at line 97 of file tld.h.

The documentation for this struct was generated from the following file:

- [tld.h](#)

4.7 TId_table_element Struct Reference

```
#include <tld.h>
```

Data Fields

- uint32_t [start](#)
- uint32_t [end](#)

4.7.1 Detailed Description

[TId_table_element](#):

Parameters

<i>start</i>	Start of range.
<i>end</i>	End of range, end == start if single.

Interval of valid code points in the TLD.

Definition at line 78 of file tld.h.

4.7.2 Field Documentation

4.7.2.1 end

```
uint32_t Tld_table_element::end
```

Definition at line 81 of file tld.h.

4.7.2.2 start

```
uint32_t Tld_table_element::start
```

Definition at line 80 of file tld.h.

The documentation for this struct was generated from the following file:

- [tld.h](#)

Chapter 5

Functions

- void [idn_free](#) (void *ptr)

5.4.1 Function Documentation

5.4.1.1 [idn_free\(\)](#)

```
void idn_free (
    void * ptr )
```

idn_free:

Parameters

<i>ptr</i>	memory region to deallocate, or NULL.
------------	---------------------------------------

Deallocates memory region by calling free(). If @ptr is NULL no operation is performed.

Normally applications de-allocate strings allocated by libidn by calling free() directly. Under Windows, different parts of the same application may use different heap memory, and then it is important to deallocate memory allocated within the same module that allocated it. This function makes that possible.

(c) == 0xFF0E || (c) == 0xFF61)
```

Value:

Definition at line 44 of file idna.c.

5.7.2 Function Documentation

5.7.2.1 idna_to_ascii_4i()

```
int idna_to_ascii_4i (
    const uint32_t * in,
    size_t inlen,
    char * out,
    int flags )
```

idna_to_ascii_4i:

Parameters

<i>in</i>	input array with unicode code points.
<i>inlen</i>	length of input array with unicode code points.
<i>out</i>	output zero terminated string that must have room for at least 63 characters plus the terminating zero.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

The ToASCII operation takes a sequence of Unicode code points that make up one domain label and transforms it into a sequence of code points in the ASCII range (0..7F). If ToASCII succeeds, the original sequence and the resulting sequence are equivalent labels.

It is important to note that the ToASCII operation can fail. ToASCII fails if any step of it fails. If any step of the ToASCII operation fails on any label in a domain name, that domain name MUST NOT be used as an internationalized domain name. The method for dealing with this failure is application-specific.

The inputs to ToASCII are a sequence of code points, the AllowUnassigned flag, and the UseSTD3ASCIIRules flag. The output of ToASCII is either a sequence of ASCII code points or a failure condition.

ToASCII never alters a sequence of code points that are all in the ASCII range to begin with (although it could fail). Applying the ToASCII operation multiple times has exactly the same effect as applying it just once.

Return value: Returns 0 on success, or an [Idna_rc](#) error code.

Definition at line 81 of file idna.c.

5.7.2.2 idna_to_ascii_4z()

```
int idna_to_ascii_4z (
    const uint32_t * input,
    char ** output,
    int flags )
```

idna_to_ascii_4z:

Parameters

<i>input</i>	zero terminated input Unicode string.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert UCS-4 domain name to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 477 of file idna.c.

5.7.2.3 idna_to_ascii_8z()

```
int idna_to_ascii_8z (
    const char * input,
    char ** output,
    int flags )
```

idna_to_ascii_8z:

Parameters

<i>input</i>	zero terminated input UTF-8 string.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert UTF-8 domain name to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 576 of file idna.c.

5.7.2.4 idna_to_ascii_lz()

```
int idna_to_ascii_lz (
    const char * input,
```

```
    char ** output,
    int flags )
```

idna_to_ascii_lz:

Parameters

<i>input</i>	zero terminated input string encoded in the current locale's character set.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert domain name in the locale's encoding to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 609 of file idna.c.

5.7.2.5 idna_to_unicode_44i()

```
int idna_to_unicode_44i (
    const uint32_t * in,
    size_t inlen,
    uint32_t * out,
    size_t * outlen,
    int flags )
```

idna_to_unicode_44i:

Parameters

<i>in</i>	input array with unicode code points.
<i>inlen</i>	length of input array with unicode code points.
<i>out</i>	output array with unicode code points.
<i>outlen</i>	on input, maximum size of output array with unicode code points, on exit, actual size of output array with unicode code points.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

The ToUnicode operation takes a sequence of Unicode code points that make up one domain label and returns a sequence of Unicode code points. If the input sequence is a label in ACE form, then the result is an equivalent internationalized label that is not in ACE form, otherwise the original sequence is returned unaltered.

ToUnicode never fails. If any step fails, then the original input sequence is returned immediately in that step.

The Punycode decoder can never output more code points than it inputs, but Nameprep can, and therefore To←Unicode can. Note that the number of octets needed to represent a sequence of code points depends on the particular character encoding used.

The inputs to ToUnicode are a sequence of code points, the AllowUnassigned flag, and the UseSTD3ASCIIRules flag. The output of ToUnicode is always a sequence of Unicode code points.

Return value: Returns [Idna_rc](#) error condition, but it must only be used for debugging purposes. The output buffer is always guaranteed to contain the correct data according to the specification (sans malloc induced errors). NB! This means that you normally ignore the return code from this function, as checking it means breaking the standard.

Definition at line 437 of file idna.c.

5.7.2.6 [idna_to_unicode_4z4z\(\)](#)

```
int idna_to_unicode_4z4z (
    const uint32_t * input,
    uint32_t ** output,
    int flags )
```

[idna_to_unicode_4z4z](#):

Parameters

<i>input</i>	zero-terminated Unicode string.
<i>output</i>	pointer to newly allocated output Unicode string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UCS-4 format into a UCS-4 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 640 of file idna.c.

5.7.2.7 [idna_to_unicode_8z4z\(\)](#)

```
int idna_to_unicode_8z4z (
    const char * input,
    uint32_t ** output,
    int flags )
```

[idna_to_unicode_8z4z](#):

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output Unicode string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a UCS-4 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 719 of file idna.c.

5.7.2.8 idna_to_unicode_8z8z()

```
int idna_to_unicode_8z8z (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_8z8z:

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output UTF-8 string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a UTF-8 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 750 of file idna.c.

5.7.2.9 idna_to_unicode_8zlz()

```
int idna_to_unicode_8zlz (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_8zlz:

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output string encoded in the current locale's character set.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a string encoded in the current locale's character set. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 784 of file idna.c.

5.7.2.10 idna_to_unicode_lzlz()

```
int idna_to_unicode_lzlz (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_lzlz:

Parameters

<i>input</i>	zero-terminated string encoded in the current locale's character set.
<i>output</i>	pointer to newly allocated output string encoded in the current locale's character set.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in the locale's character set into a string encoded in the current locale's character set. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 819 of file idna.c.

5.8.3 Function Documentation

5.8.3.1 idna_strerror()

```
IDNAPI const char* idna_strerror (
    Idna_rc rc )
```

idna_strerror:

Parameters

<code>rc</code>	an Idna_rc return code.
-----------------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

IDNA_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. IDNA_STRINGPREP_ERROR: Error during string preparation. IDNA_PUNYCODE_ERROR: Error during punycode operation. IDNA_CONTAINS_NON_LDH: For IDNA_USE_STD3_ASCII_RULES, indicate that the string contains non-LDH ASCII characters. IDNA_CONTAINS_MINUS: For IDNA_USE_STD3_ASCII_RULES, indicate that the string contains a leading or trailing hyphen-minus (U+002D). IDNA_INVALID_LENGTH: The final output string is not within the (inclusive) range 1 to 63 characters. IDNA_NO_ACE_PREFIX: The string does not contain the ACE prefix (for ToUnicode). IDNA_ROUNDTRIP_VERIFY_ERROR: The ToASCII operation on output string does not equal the input. IDNA_CONTAINS_ACE_PREFIX: The input contains the ACE prefix (for ToASCII). IDNA_ICONV_ERROR: Character encoding conversion error. IDNA_MALLOC_ERROR: Could not allocate buffer (this is typically a fatal error). IDNA_DLOPEN_ERROR: Could not dlopen the libcidn DSO (only used internally in libc).

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 73 of file strerror-idna.c.

5.8.3.2 idna_to_ascii_4i()

```
IDNAPI int idna_to_ascii_4i (
    const uint32_t * in,
    size_t inlen,
    char * out,
    int flags )
```

idna_to_ascii_4i:

Parameters

<code>in</code>	input array with unicode code points.
<code>inlen</code>	length of input array with unicode code points.
<code>out</code>	output zero terminated string that must have room for at least 63 characters plus the terminating zero.
<code>flags</code>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

The ToASCII operation takes a sequence of Unicode code points that make up one domain label and transforms it into a sequence of code points in the ASCII range (0..7F). If ToASCII succeeds, the original sequence and the resulting sequence are equivalent labels.

It is important to note that the ToASCII operation can fail. ToASCII fails if any step of it fails. If any step of the ToASCII operation fails on any label in a domain name, that domain name MUST NOT be used as an internationalized domain name. The method for dealing with this failure is application-specific.

The inputs to ToASCII are a sequence of code points, the AllowUnassigned flag, and the UseSTD3ASCIIRules flag. The output of ToASCII is either a sequence of ASCII code points or a failure condition.

ToASCII never alters a sequence of code points that are all in the ASCII range to begin with (although it could fail). Applying the ToASCII operation multiple times has exactly the same effect as applying it just once.

Return value: Returns 0 on success, or an [Idna_rc](#) error code.

Definition at line 81 of file idna.c.

5.8.3.3 [idna_to_ascii_4z\(\)](#)

```
IDNAPI int idna_to_ascii_4z (
    const uint32_t * input,
    char ** output,
    int flags )
```

[idna_to_ascii_4z](#):

Parameters

<i>input</i>	zero terminated input Unicode string.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert UCS-4 domain name to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 477 of file idna.c.

5.8.3.4 [idna_to_ascii_8z\(\)](#)

```
IDNAPI int idna_to_ascii_8z (
    const char * input,
    char ** output,
    int flags )
```

[idna_to_ascii_8z](#):

Parameters

<i>input</i>	zero terminated input UTF-8 string.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert UTF-8 domain name to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 576 of file idna.c.

5.8.3.5 idna_to_ascii_lz()

```
IDNAPI int idna_to_ascii_lz (
    const char * input,
    char ** output,
    int flags )
```

idna_to_ascii_lz:

Parameters

<i>input</i>	zero terminated input string encoded in the current locale's character set.
<i>output</i>	pointer to newly allocated output string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert domain name in the locale's encoding to ASCII string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 609 of file idna.c.

5.8.3.6 idna_to_unicode_44i()

```
IDNAPI int idna_to_unicode_44i (
    const uint32_t * in,
    size_t inlen,
    uint32_t * out,
    size_t * outlen,
    int flags )
```

idna_to_unicode_44i:

Parameters

<i>in</i>	input array with unicode code points.
<i>inlen</i>	length of input array with unicode code points.
<i>out</i>	output array with unicode code points.
<i>outlen</i>	on input, maximum size of output array with unicode code points, on exit, actual size of output array with unicode code points.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

The ToUnicode operation takes a sequence of Unicode code points that make up one domain label and returns a

sequence of Unicode code points. If the input sequence is a label in ACE form, then the result is an equivalent internationalized label that is not in ACE form, otherwise the original sequence is returned unaltered.

ToUnicode never fails. If any step fails, then the original input sequence is returned immediately in that step.

The Punycode decoder can never output more code points than it inputs, but Nameprep can, and therefore To←Unicode can. Note that the number of octets needed to represent a sequence of code points depends on the particular character encoding used.

The inputs to ToUnicode are a sequence of code points, the AllowUnassigned flag, and the UseSTD3ASCIIRules flag. The output of ToUnicode is always a sequence of Unicode code points.

Return value: Returns [Idna_rc](#) error condition, but it must only be used for debugging purposes. The output buffer is always guaranteed to contain the correct data according to the specification (sans malloc induced errors). NB! This means that you normally ignore the return code from this function, as checking it means breaking the standard.

Definition at line 437 of file idna.c.

5.8.3.7 idna_to_unicode_4z4z()

```
IDNAPI int idna_to_unicode_4z4z (
    const uint32_t * input,
    uint32_t ** output,
    int flags )
```

idna_to_unicode_4z4z:

Parameters

<i>input</i>	zero-terminated Unicode string.
<i>output</i>	pointer to newly allocated output Unicode string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UCS-4 format into a UCS-4 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 640 of file idna.c.

5.8.3.8 idna_to_unicode_8z4z()

```
IDNAPI int idna_to_unicode_8z4z (
    const char * input,
    uint32_t ** output,
    int flags )
```

idna_to_unicode_8z4z:

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output Unicode string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a UCS-4 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 719 of file idna.c.

5.8.3.9 idna_to_unicode_8z8z()

```
IDNAPI int idna_to_unicode_8z8z (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_8z8z:

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output UTF-8 string.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a UTF-8 string. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 750 of file idna.c.

5.8.3.10 idna_to_unicode_8zlz()

```
IDNAPI int idna_to_unicode_8zlz (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_8zlz:

Parameters

<i>input</i>	zero-terminated UTF-8 string.
<i>output</i>	pointer to newly allocated output string encoded in the current locale's character set.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in UTF-8 format into a string encoded in the current locale's character set. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 784 of file idna.c.

5.8.3.11 idna_to_unicode_lzlz()

```
IDNAPI int idna_to_unicode_lzlz (
    const char * input,
    char ** output,
    int flags )
```

idna_to_unicode_lzlz:

Parameters

<i>input</i>	zero-terminated string encoded in the current locale's character set.
<i>output</i>	pointer to newly allocated output string encoded in the current locale's character set.
<i>flags</i>	an Idna_flags value, e.g., IDNA_ALLOW_UNASSIGNED or IDNA_USE_STD3_ASCII_RULES.

Convert possibly ACE encoded domain name in the locale's character set into a string encoded in the current locale's character set. The domain name may contain several labels, separated by dots. The output buffer must be deallocated by the caller.

Return value: Returns IDNA_SUCCESS on success, or error code.

Definition at line 819 of file idna.c.

G_NORMALIZE_NFKC	

Definition at line 114 of file nfkc.c.

5.9.3 Function Documentation

5.9.3.1 stringprep_ucs4_nfkc_normalize()

```
uint32_t* stringprep_ucs4_nfkc_normalize (
    const uint32_t * str,
    ssize_t len )
```

stringprep_ucs4_nfkc_normalize:

Parameters

<i>str</i>	a Unicode string.
<i>len</i>	length of @str array, or -1 if @str is nul-terminated.

Converts a UCS4 string into canonical form, see [stringprep_utf8_nfkc_normalize\(\)](#) for more information.

Return value: a newly allocated Unicode string, that is the NFKC normalized form of @str.

Definition at line 1096 of file nfkc.c.

5.9.3.2 stringprep_ucs4_to_utf8()

```
char* stringprep_ucs4_to_utf8 (
    const uint32_t * str,
    ssize_t len,
    size_t * items_read,
    size_t * items_written )
```

stringprep_ucs4_to_utf8:

Parameters

<i>str</i>	a UCS-4 encoded string
<i>len</i>	the maximum length of @str to use. If @len < 0, then the string is terminated with a 0 character.
<i>items_read</i>	location to store number of characters read read, or NULL.
<i>items_written</i>	location to store number of bytes written or NULL. The value here stored does not include the trailing 0 byte.

Convert a string from a 32-bit fixed width representation as UCS-4. to UTF-8. The result will be terminated with a 0 byte.

Return value: a pointer to a newly allocated UTF-8 string. This value must be deallocated by the caller. If an error occurs, NULL will be returned.

Definition at line 1039 of file nfkc.c.

5.9.3.3 stringprep_unichar_to_utf8()

```
int stringprep_unichar_to_utf8 (
    uint32_t c,
    char * outbuf )
```

stringprep_unichar_to_utf8:

Parameters

<i>c</i>	a ISO10646 character code
<i>outbuf</i>	output buffer, must have at least 6 bytes of space. If NULL, the length will be computed and returned and nothing will be written to @outbuf.

Converts a single character to UTF-8.

Return value: number of bytes written.

Definition at line 982 of file nfkc.c.

5.9.3.4 stringprep_utf8_nfkc_normalize()

```
char* stringprep_utf8_nfkc_normalize (
    const char * str,
    ssize_t len )
```

stringprep_utf8_nfkc_normalize:

Parameters

<i>str</i>	a UTF-8 encoded string.
<i>len</i>	length of @str, in bytes, or -1 if @str is nul-terminated.

Converts a string into canonical form, standardizing such issues as whether a character with an accent is represented as a base character and combining accent or as a single precomposed character.

The normalization mode is NFKC (ALL COMPOSE). It standardizes differences that do not affect the text content, such as the above-mentioned accent representation. It standardizes the "compatibility" characters in Unicode, such as SUPERSCRIPT THREE to the standard forms (in this case DIGIT THREE). Formatting information may be lost but for most text operations such characters should be considered the same. It returns a result with composed forms rather than a maximally decomposed form.

Return value: a newly allocated string, that is the NFKC normalized form of @str.

Definition at line 1068 of file nfkc.c.

5.9.3.5 stringprep_utf8_to_ucs4()

```
uint32_t* stringprep_utf8_to_ucs4 (
    const char * str,
    ssize_t len,
    size_t * items_written )
```

stringprep_utf8_to_ucs4:

Parameters

<i>str</i>	a UTF-8 encoded string
<i>len</i>	the maximum length of @str to use. If @len < 0, then the string is nul-terminated.
<i>items_written</i>	location to store the number of characters in the result, or NULL.

Convert a string from UTF-8 to a 32-bit fixed width representation as UCS-4. The function now performs error checking to verify that the input is valid UTF-8 (before it was documented to not do error checking).

Return value: a pointer to a newly allocated UCS-4 string. This value must be deallocated by the caller.

Definition at line 1006 of file nfkc.c.

5.9.3.6 `stringprep_utf8_to_unichar()`

```
uint32_t stringprep_utf8_to_unichar (
    const char * p )
```

`stringprep_utf8_to_unichar:`

Parameters

<i>p</i>	a pointer to Unicode character encoded as UTF-8
----------	---

Converts a sequence of bytes encoded as UTF-8 to a Unicode character. If does not point to a valid UTF-8 encoded character, results are undefined.

Return value: the resulting character.

Definition at line 965 of file nfkc.c.

5.10 pr29.c File Reference

5.10.1.1 `pr29_4()`

```
int pr29_4 (
    const uint32_t * in,
    size_t len )
```

`pr29_4:`

Parameters

<i>in</i>	input array with unicode code points.
<i>len</i>	length of input array with unicode code points.

Check the input to see if it may be normalized into different strings by different NFKC implementations, due to an anomaly in the NFKC specifications.

Return value: Returns the [Pr29_rc](#) value PR29_SUCCESS on success, and PR29_PROBLEM if the input sequence is a "problem sequence" (i.e., may be normalized into different strings by different implementations).

Definition at line 1247 of file pr29.c.

5.10.1.2 pr29_4z()

```
int pr29_4z (
    const uint32_t * in )
```

pr29_4z:

Parameters

<i>in</i>	zero terminated array of Unicode code points.
-----------	---

Check the input to see if it may be normalized into different strings by different NFKC implementations, due to an anomaly in the NFKC specifications.

Return value: Returns the [Pr29_rc](#) value PR29_SUCCESS on success, and PR29_PROBLEM if the input sequence is a "problem sequence" (i.e., may be normalized into different strings by different implementations).

Definition at line 1288 of file pr29.c.

5.10.1.3 pr29_8z()

```
int pr29_8z (
    const char * in )
```

pr29_8z:

Parameters

<i>in</i>	zero terminated input UTF-8 string.
-----------	-------------------------------------

Check the input to see if it may be normalized into different strings by different NFKC implementations, due to an anomaly in the NFKC specifications.

Return value: Returns the [Pr29_rc](#) value PR29_SUCCESS on success, and PR29_PROBLEM if the input sequence is a "problem sequence" (i.e., may be normalized into different strings by different implementations), or PR29_STRINGPREP_ERROR if there was a problem converting the string from UTF-8 to UCS-4.

```
IDNAPI int pr29_8z (
    const char * in )
```

pr29_8z:

Parameters

<i>in</i>	zero terminated input UTF-8 string.
-----------	-------------------------------------

Check the input to see if it may be normalized into different strings by different NFKC implementations, due to an anomaly in the NFKC specifications.

Return value: Returns the [Pr29_rc](#) value PR29_SUCCESS on success, and PR29_PROBLEM if the input sequence is a "problem sequence" (i.e., may be normalized into different strings by different implementations), or PR29_STRINGPREP_ERROR if there was a problem converting the string from UTF-8 to UCS-4.

Definition at line 1313 of file pr29.c.

5.11.3.4 pr29_strerror()

```
IDNAPI const char* pr29_strerror (
    Pr29_rc rc )
```

pr29_strerror:

Parameters

<i>rc</i>	an Pr29_rc return code.
-----------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

PR29_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only

guaranteed to hold non-zero values, for logical comparison purposes. PR29_PROBLEM: A problem sequence was encountered. PR29_STRINGPREP_ERROR: The character set conversion failed (only for [pr29_8z\(\)](#)).

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 57 of file strerror-pr29.c.

5.13.3 Function Documentation

5.13.3.1 punycode_decode()

```
int punycode_decode (
    size_t input_length,
    const char input[],
    size_t * output_length,
    punycode_uint output[],
    unsigned char case_flags[] )
```

punycode_decode:

Parameters

<i>input_length</i>	The number of ASCII code points in the @input array.
<i>input</i>	An array of ASCII code points (0..7F).

Parameters

<i>output_length</i>	The caller passes in the maximum number of code points that it can receive into the @output array (which is also the maximum number of flags that it can receive into the @case_flags array, if @case_flags is not a NULL pointer). On successful return it will contain the number of code points actually output (which is also the number of flags actually output, if case_flags is not a null pointer). The decoder will never need to output more code points than the number of ASCII code points in the input, because of the way the encoding is defined. The number of code points output cannot exceed the maximum possible value of a punycode_uint, even if the supplied @output_length is greater than that.
<i>output</i>	An array of code points like the input argument of punycode_encode() (see above).
<i>case_flags</i>	A NULL pointer (if the flags are not needed by the caller) or an array of boolean values parallel to the @output array. Nonzero (true, flagged) suggests that the corresponding Unicode character be forced to uppercase by the caller (if possible), and zero (false, unflagged) suggests that it be forced to lowercase (if possible). ASCII code points (0..7F) are output already in the proper case, but their flags will be set appropriately so that applying the flags would be harmless.

Converts Punycode to a sequence of code points (presumed to be Unicode code points).

Return value: The return value can be any of the [Punycode_status](#) values defined above. If not PUNYCODE_SUCCESS, then @output_length, @output, and @case_flags might contain garbage.

Definition at line 348 of file punycode.c.

5.13.3.2 [punycode_encode\(\)](#)

```
int punycode_encode (
    size_t input_length,
    const punycode_uint input[],
    const unsigned char case_flags[],
    size_t * output_length,
    char output[] )
```

[punycode_encode](#):

Parameters

<i>input_length</i>	The number of code points in the @input array and the number of flags in the @case_flags array.
<i>input</i>	An array of code points. They are presumed to be Unicode code points, but that is not strictly REQUIRED. The array contains code points, not code units. UTF-16 uses code units D800 through DFFF to refer to code points 10000..10FFFF. The code points D800..DFFF do not occur in any valid Unicode string. The code points that can occur in Unicode strings (0..D7FF and E000..10FFFF) are also called Unicode scalar values.
<i>case_flags</i>	A NULL pointer or an array of boolean values parallel to the @input array. Nonzero (true, flagged) suggests that the corresponding Unicode character be forced to uppercase after being decoded (if possible), and zero (false, unflagged) suggests that it be forced to lowercase (if possible). ASCII code points (0..7F) are encoded literally, except that ASCII letters are forced to uppercase or lowercase according to the corresponding case flags. If @case_flags is a NULL pointer then ASCII letters are left as they are, and other code points are treated as unflagged.
<i>output_length</i>	The caller passes in the maximum number of ASCII code points that it can receive. On successful return it will contain the number of ASCII code points actually output.
Generated by Doxygen output	An array of ASCII code points. It is <i>not</i> null-terminated; it will contain zeros if and only if the @input contains zeros. (Of course the caller can leave room for a terminator and add one if needed.)

Converts a sequence of code points (presumed to be Unicode code points) to Punycode.

Return value: The return value can be any of the [Punycode_status](#) values defined above except PUNYCODE_BAD_INPUT. If not PUNYCODE_SUCCESS, then @output_size and @output might contain garbage.

Definition at line 196 of file punycode.c.

5.14.3.2 Punycode_status

```
enum Punycode_status
```

Enumerator

<code>PUNYCODE_SUCCESS</code>	<input type="checkbox"/>
-------------------------------	--------------------------

Enumerator

PUNYCODE_BAD_INPUT	
PUNYCODE_BIG_OUTPUT	
PUNYCODE_OVERFLOW	

Definition at line 108 of file punycode.h.

5.14.4 Function Documentation

5.14.4.1 punycode_decode()

```
IDNAPI int punycode_decode (
    size_t input_length,
    const char input[],
    size_t * output_length,
    punycode_uint output[],
    unsigned char case_flags[] )
```

punycode_decode:

Parameters

<i>input_length</i>	The number of ASCII code points in the @input array.
<i>input</i>	An array of ASCII code points (0..7F).
<i>output_length</i>	The caller passes in the maximum number of code points that it can receive into the @output array (which is also the maximum number of flags that it can receive into the @case_flags array, if @case_flags is not a NULL pointer). On successful return it will contain the number of code points actually output (which is also the number of flags actually output, if case_flags is not a null pointer). The decoder will never need to output more code points than the number of ASCII code points in the input, because of the way the encoding is defined. The number of code points output cannot exceed the maximum possible value of a punycode_uint, even if the supplied @output_length is greater than that.
<i>output</i>	An array of code points like the input argument of punycode_encode() (see above).
<i>case_flags</i>	A NULL pointer (if the flags are not needed by the caller) or an array of boolean values parallel to the @output array. Nonzero (true, flagged) suggests that the corresponding Unicode character be forced to uppercase by the caller (if possible), and zero (false, unflagged) suggests that it be forced to lowercase (if possible). ASCII code points (0..7F) are output already in the proper case, but their flags will be set appropriately so that applying the flags would be harmless.

Converts Punycode to a sequence of code points (presumed to be Unicode code points).

Return value: The return value can be any of the [Punycode_status](#) values defined above. If not PUNYCODE_SUCCESS, then @output_length, @output, and @case_flags might contain garbage.

Definition at line 348 of file punycode.c.

5.14.4.2 punycode_encode()

```
IDNAPI int punycode_encode (
    size_t input_length,
    const punycode_uint input[],
    const unsigned char case_flags[],
    size_t * output_length,
    char output[] )
```

punycode_encode:

Parameters

<i>input_length</i>	The number of code points in the @input array and the number of flags in the @case_flags array.
<i>input</i>	An array of code points. They are presumed to be Unicode code points, but that is not strictly REQUIRED. The array contains code points, not code units. UTF-16 uses code units D800 through DFFF to refer to code points 10000..10FFFF. The code points D800..DFFF do not occur in any valid Unicode string. The code points that can occur in Unicode strings (0..D7FF and E000..10FFFF) are also called Unicode scalar values.
<i>case_flags</i>	A NULL pointer or an array of boolean values parallel to the @input array. Nonzero (true, flagged) suggests that the corresponding Unicode character be forced to uppercase after being decoded (if possible), and zero (false, unflagged) suggests that it be forced to lowercase (if possible). ASCII code points (0..7F) are encoded literally, except that ASCII letters are forced to uppercase or lowercase according to the corresponding case flags. If @case_flags is a NULL pointer then ASCII letters are left as they are, and other code points are treated as unflagged.
<i>output_length</i>	The caller passes in the maximum number of ASCII code points that it can receive. On successful return it will contain the number of ASCII code points actually output.
<i>output</i>	An array of ASCII code points. It is <i>not</i> null-terminated; it will contain zeros if and only if the @input contains zeros. (Of course the caller can leave room for a terminator and add one if needed.)

Converts a sequence of code points (presumed to be Unicode code points) to Punycode.

Return value: The return value can be any of the [Punycode_status](#) values defined above except PUNYCODE_BAD_INPUT. If not PUNYCODE_SUCCESS, then @output_size and @output might contain garbage.

Definition at line 196 of file punycode.c.

5.14.4.3 punycode_strerror()

```
IDNAPI const char* punycode_strerror (
    Punycode_Status rc )
```

punycode_strerror:

Parameters

<i>rc</i>	an Punycode_Status return code.
-----------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

PUNYCODE_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. PUNYCODE_BAD_INPUT: Input is invalid. PUNYCODE_BIG_OUTPUT: Output would exceed the space provided. PUNYCODE_OVERFLOW: Input needs wider integers to process.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 57 of file strerror-punycode.c.

```
const char* idna_strerror (
    Idna\_rc rc )
```

[idna_strerror](#):

Parameters

<i>rc</i>	an Idna_rc return code.
-----------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

IDNA_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. IDNA_STRINGPREP_ERROR: Error during

string preparation. IDNA_PUNYCODE_ERROR: Error during punycode operation. IDNA_CONTAINS_NON_LDH: For IDNA_USE_STD3_ASCII_RULES, indicate that the string contains non-LDH ASCII characters. IDNA_CONTAINS_MINUS: For IDNA_USE_STD3_ASCII_RULES, indicate that the string contains a leading or trailing hyphen-minus (U+002D). IDNA_INVALID_LENGTH: The final output string is not within the (inclusive) range 1 to 63 characters. IDNA_NO_ACE_PREFIX: The string does not contain the ACE prefix (for ToUnicode). IDNA_ROUNDTRIP_VERIFY_ERROR: The ToASCII operation on output string does not equal the input. IDNA_CONTAINS_ACE_PREFIX: The input contains the ACE prefix (for ToASCII). IDNA_ICONV_ERROR: Character encoding conversion error. IDNA_MALLOC_ERROR: Could not allocate buffer (this is typically a fatal error). IDNA_DLOPEN_ERROR: Could not dlopen the libcidn DSO (only used internally in libc).

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

```
#define _(
    String ) dgettext (PACKAGE, String)
```

Definition at line 37 of file strerror-pr29.c.

5.18.2 Function Documentation

5.18.2.1 pr29_strerror()

```
const char* pr29_strerror (
    Pr29_rc rc )
```

pr29_strerror:

Parameters

<code>rc</code>	an Pr29_rc return code.
-----------------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

PR29_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. PR29_PROBLEM: A problem sequence was encountered. PR29_STRINGPREP_ERROR: The character set conversion failed (only for [pr29_8z\(\)](#)).

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 57 of file strerror-pr29.c.

5.19 strerror-punycode.c File Reference

5.19.1.1 _

```
#define _(
    String ) dgettext (PACKAGE, String)
```

Definition at line 37 of file strerror-punycode.c.

5.19.2 Function Documentation

5.19.2.1 punycode_strerror()

```
const char* punycode_strerror (
    Punycode_status rc )
```

punycode_strerror:

Parameters

<i>rc</i>	an Punycode_status return code.
-----------	---

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

PUNYCODE_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. PUNYCODE_BAD_INPUT: Input is invalid. PUNYCODE_BIG_OUTPUT: Output would exceed the space provided. PUNYCODE_OVERFLOW: Input needs wider integers to process.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 57 of file strerror-punycode.c.

5.20.2 Function Documentation

5.20.2.1 stringprep_strerror()

```
const char* stringprep_strerror (
    Stringprep_rc rc )
```

stringprep_strerror:

Parameters

<code>rc</code>	a Stringprep_rc return code.
-----------------	--

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

STRINGPREP_OK: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. STRINGPREP_CONTAINS_UNASSIGNED: String contain unassigned Unicode code points, which is forbidden by the profile. STRINGPREP_CONTAINS_PROHIBITED: String contain code points prohibited by the profile. STRINGPREP_BIDI_BOTH_L_AND_RAL: String contain code points with conflicting bidirection category. STRINGPREP_BIDI_LEADTRAIL_NOT_RAL: Leading and trailing character in string not of proper bidirectional category. STRINGPREP_BIDI_CONTAINS_PROHIBITED: Contains prohibited code points detected by bidirectional code. STRINGPREP_TOO_SMALL_BUFFER: Buffer handed to function was too small. This usually indicate a problem in the calling application. STRINGPREP_PROFILE_ERROR: The stringprep profile was inconsistent. This usually indicate an internal error in the library. STRINGPREP_FLAG_ERROR: The supplied flag conflicted with profile. This usually indicate a problem in the calling application. STRINGPREP_UNKNOWN_PROFILE: The supplied profile name was not known to the library. STRINGPREP_ICONV_ERROR: Character encoding conversion error. STRINGPREP_NFKC_FAILED: The Unicode NFKC operation failed. This usually indicate an internal error in the library. STRINGPREP_MALLOC_ERROR: The malloc() was out of memory. This is usually a fatal error.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 78 of file strerror-stringprep.c.

5.21.2 Function Documentation

5.21.2.1 tld_strerror()

```
const char* tld_strerror (
    Tld_rc rc )
```

tld_strerror:

Parameters

<code>rc</code>	tld return code
-----------------	-----------------

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

TLD_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. TLD_INVALID: Invalid character found. TLD_NODATA: No input data was provided. TLD_MALLOC_ERROR: Error during memory allocation. TLD_ICONV_ERROR: Character encoding conversion error. TLD_NO_TLD: No top-level domain found in domain string.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 59 of file strerror-tld.c.

- int `stringprep` (char *in, size_t maxlen, `Stringprep_profile_flags` flags, const `Stringprep_profile` *profile)
- int `stringprep_profile` (const char *in, char **out, const char *profile, `Stringprep_profile_flags` flags)

5.22.1 Macro Definition Documentation

```
#define INVERTED(
    x ) ((x) & ((~0UL) >> 1))
```

Definition at line 144 of file stringprep.c.

5.22.1.2 UNAPPLICABLEFLAGS

```
#define UNAPPLICABLEFLAGS (
    flags,
    profileflags )
```

Value:

```
(( !INVERTED(profileflags) && !(profileflags & flags) && profileflags) || \
( INVERTED(profileflags) && (profileflags & flags)))
```

Definition at line 145 of file stringprep.c.

5.22.2 Function Documentation

5.22.2.1 stringprep()

```
int stringprep (
    char * in,
    size_t maxlen,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep:

Parameters

<i>in</i>	input/output array with string to prepare.
<i>maxlen</i>	maximum length of input/output array.
<i>flags</i>	a <code>Stringprep_profile_flags</code> value, or 0.
<i>profile</i>	pointer to <code>Stringprep_profile</code> to use.

Prepare the input zero terminated UTF-8 string according to the stringprep profile, and write back the result to the input string.

Note that you must convert strings entered in the systems locale into UTF-8 before using this function, see [stringprep_locale_to_utf8\(\)](#).

Since the stringprep operation can expand the string, @maxlen indicate how large the buffer holding the string is. This function will not read or write to characters outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an error code.

Definition at line 414 of file stringprep.c.

5.22.2.2 stringprep_4i()

```
int stringprep_4i (
    uint32_t * ucs4,
    size_t * len,
    size_t maxucs4len,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep_4i:

Parameters

<i>ucs4</i>	input/output array with string to prepare.
<i>len</i>	on input, length of input array with Unicode code points, on exit, length of output array with Unicode code points.
<i>maxucs4len</i>	maximum length of input/output array.
<i>flags</i>	a Stringprep_profile_flags value, or 0.
<i>profile</i>	pointer to Stringprep_profile to use.

Prepare the input UCS-4 string according to the stringprep profile, and write back the result to the input string.

The input is not required to be zero terminated (@ucs4[@len] = 0). The output will not be zero terminated unless @ucs4[@len] = 0. Instead, see [stringprep_4zi\(\)](#) if your input is zero terminated or if you want the output to be.

Since the stringprep operation can expand the string, @maxucs4len indicate how large the buffer holding the string is. This function will not read or write to code points outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an [Stringprep_rc](#) error code.

Definition at line 181 of file stringprep.c.

5.22.2.3 stringprep_4zi()

```
int stringprep_4zi (
    uint32_t * ucs4,
    size_t maxucs4len,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep_4zi:

Parameters

<i>ucs4</i>	input/output array with zero terminated string to prepare.
<i>maxucs4len</i>	maximum length of input/output array.
<i>flags</i>	a Stringprep_profile_flags value, or 0.
<i>profile</i>	pointer to Stringprep_profile to use.

Prepare the input zero terminated UCS-4 string according to the stringprep profile, and write back the result to the input string.

Since the stringprep operation can expand the string, @maxucs4len indicate how large the buffer holding the string is. This function will not read or write to code points outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an [Stringprep_rc](#) error code.

Definition at line 374 of file stringprep.c.

5.22.2.4 stringprep_profile()

```
int stringprep_profile (
    const char * in,
    char ** out,
    const char * profile,
    Stringprep_profile_flags flags )
```

stringprep_profile:

Parameters

<i>in</i>	input array with UTF-8 string to prepare.
<i>out</i>	output variable with pointer to newly allocate string.
<i>profile</i>	name of stringprep profile to use.
<i>flags</i>	a Stringprep_profile_flags value, or 0.

Prepare the input zero terminated UTF-8 string according to the stringprep profile, and return the result in a newly allocated variable.

Note that you must convert strings entered in the systems locale into UTF-8 before using this function, see [stringprep_locale_to_utf8\(\)](#).

The @out variable must be deallocated by the caller.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile specifies the name of the stringprep profile to use. It must be one of the internally supported stringprep profiles.

Return value: Returns STRINGPREP_OK iff successful, or an error code.

Definition at line 493 of file stringprep.c.

5.23 stringprep.h File Reference

5.23.4 Function Documentation

5.23.4.1 stringprep()

```
IDNAPI int stringprep (
    char * in,
    size_t maxlen,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep:

Parameters

<i>in</i>	input/output array with string to prepare.
<i>maxlen</i>	maximum length of input/output array.
<i>flags</i>	a Stringprep_profile_flags value, or 0.
<i>profile</i>	pointer to Stringprep_profile to use.

Prepare the input zero terminated UTF-8 string according to the stringprep profile, and write back the result to the input string.

Note that you must convert strings entered in the systems locale into UTF-8 before using this function, see [stringprep_locale_to_utf8\(\)](#).

Since the stringprep operation can expand the string, @maxlen indicate how large the buffer holding the string is. This function will not read or write to characters outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an error code.

Definition at line 414 of file stringprep.c.

5.23.4.2 stringprep_4i()

```
IDNAPI int stringprep_4i (
    uint32_t * ucs4,
    size_t * len,
    size_t maxucs4len,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep_4i:

Parameters

<i>ucs4</i>	input/output array with string to prepare.
<i>len</i>	on input, length of input array with Unicode code points, on exit, length of output array with Unicode code points.
<i>maxucs4len</i>	maximum length of input/output array.
<i>flags</i>	a Stringprep_profile_flags value, or 0.
<i>profile</i>	pointer to Stringprep_profile to use.

Prepare the input UCS-4 string according to the stringprep profile, and write back the result to the input string.

The input is not required to be zero terminated (@ucs4[@len] = 0). The output will not be zero terminated unless @ucs4[@len] = 0. Instead, see [stringprep_4zi\(\)](#) if your input is zero terminated or if you want the output to be.

Since the stringprep operation can expand the string, @maxucs4len indicate how large the buffer holding the string is. This function will not read or write to code points outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an [Stringprep_rc](#) error code.

Definition at line 181 of file stringprep.c.

5.23.4.3 stringprep_4zi()

```
IDNAPI int stringprep_4zi (
    uint32_t * ucs4,
    size_t maxucs4len,
    Stringprep_profile_flags flags,
    const Stringprep_profile * profile )
```

stringprep_4zi:

Parameters

<i>ucs4</i>	input/output array with zero terminated string to prepare.
<i>maxucs4len</i>	maximum length of input/output array.
<i>flags</i>	a Stringprep_profile_flags value, or 0.
<i>profile</i>	pointer to Stringprep_profile to use.

Prepare the input zero terminated UCS-4 string according to the stringprep profile, and write back the result to the input string.

Since the stringprep operation can expand the string, @maxucs4len indicate how large the buffer holding the string is. This function will not read or write to code points outside that size.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile contain the [Stringprep_profile](#) instructions to perform. Your application can define new profiles, possibly re-using the generic stringprep tables that always will be part of the library, or use one of the currently supported profiles.

Return value: Returns STRINGPREP_OK iff successful, or an [Stringprep_rc](#) error code.

Definition at line 374 of file stringprep.c.

5.23.4.4 stringprep_check_version()

```
IDNAPI const char* stringprep_check_version (
    const char * req_version )
```

stringprep_check_version:

Parameters

<i>req_version</i>	Required version number, or NULL.
--------------------	-----------------------------------

Check that the version of the library is at minimum the requested one and return the version string; return NULL if the condition is not satisfied. If a NULL is passed to this function, no check is done, but the version string is simply returned.

See STRINGPREP_VERSION for a suitable @req_version string.

Return value: Version string of run-time library, or NULL if the run-time library does not meet the required version number.

Definition at line 53 of file version.c.

5.23.4.5 stringprep_convert()

```
IDNAPI char* stringprep_convert (
    const char * str,
    const char * to_codeset,
    const char * from_codeset )
```

stringprep_convert:

Parameters

<i>str</i>	input zero-terminated string.
<i>to_codeset</i>	name of destination character set.
<i>from_codeset</i>	name of origin character set, as used by @str.

Convert the string from one character set to another using the system's iconv() function.

Return value: Returns newly allocated zero-terminated string which is @str transcoded into to_codeset.

Definition at line 116 of file toutf8.c.

5.23.4.6 stringprep_locale_charset()

```
IDNAPI const char* stringprep_locale_charset (
    void )
```

stringprep_locale_charset:

Find out current locale charset. The function respect the CHARSET environment variable, but typically uses nl_langinfo(CODESET) when it is supported. It fall back on "ASCII" if CHARSET isn't set and nl_langinfo isn't supported or return anything.

Note that this function return the application's locale's preferred charset (or thread's locale's preferred charset, if your system support thread-specific locales). It does not return what the system may be using. Thus, if you receive data from external sources you cannot in general use this function to guess what charset it is encoded in. Use stringprep_convert from the external representation into the charset returned by this function, to have data in the locale encoding.

Return value: Return the character set used by the current locale. It will never return NULL, but use "ASCII" as a fallback.

Definition at line 85 of file toutf8.c.

5.23.4.7 stringprep_locale_to_utf8()

```
IDNAPI char* stringprep_locale_to_utf8 (
    const char * str )
```

stringprep_locale_to_utf8:

Parameters

<code>str</code>	input zero terminated string.
------------------	-------------------------------

Convert string encoded in the locale's character set into UTF-8 by using [stringprep_convert\(\)](#).

Return value: Returns newly allocated zero-terminated string which is @str transcoded into UTF-8.

Definition at line 145 of file toutf8.c.

5.23.4.8 stringprep_profile()

```
IDNAPI int stringprep_profile (
    const char * in,
    char ** out,
    const char * profile,
    Stringprep_profile_flags flags )
```

stringprep_profile:

Parameters

<code>in</code>	input array with UTF-8 string to prepare.
<code>out</code>	output variable with pointer to newly allocate string.
<code>profile</code>	name of stringprep profile to use.
<code>flags</code>	a Stringprep_profile_flags value, or 0.

Prepare the input zero terminated UTF-8 string according to the stringprep profile, and return the result in a newly allocated variable.

Note that you must convert strings entered in the systems locale into UTF-8 before using this function, see [stringprep_locale_to_utf8\(\)](#).

The output @out variable must be deallocated by the caller.

The @flags are one of [Stringprep_profile_flags](#) values, or 0.

The @profile specifies the name of the stringprep profile to use. It must be one of the internally supported stringprep profiles.

Return value: Returns STRINGPREP_OK iff successful, or an error code.

Definition at line 493 of file stringprep.c.

5.23.4.9 stringprep_strerror()

```
IDNAPI const char* stringprep_strerror (
    Stringprep_rc rc )
```

stringprep_strerror:

Parameters

<code>rc</code>	a Stringprep_rc return code.
-----------------	--

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

`STRINGPREP_OK`: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. `STRINGPREP_CONTAINS_UNASSIGNED`: String contain unassigned Unicode code points, which is forbidden by the profile. `STRINGPREP_CONTAINS_PROHIBITED`: String contain code points prohibited by the profile. `STRINGPREP_BIDI_BOTH_L_AND_RAL`: String contain code points with conflicting bidirection category. `STRINGPREP_BIDI_LEADTRAIL_NOT_RAL`: Leading and trailing character in string not of proper bidirectional category. `STRINGPREP_BIDI_CONTAINS_PROHIBITED`: Contains prohibited code points detected by bidirectional code. `STRINGPREP_TOO_SMALL_BUFFER`: Buffer handed to function was too small. This usually indicate a problem in the calling application. `STRINGPREP_PROFILE_ERROR`: The stringprep profile was inconsistent. This usually indicate an internal error in the library. `STRINGPREP_FLAG_ERROR`: The supplied flag conflicted with profile. This usually indicate a problem in the calling application. `STRINGPREP_UNKNOWN_PROFILE`: The supplied profile name was not known to the library. `STRINGPREP_ICONV_ERROR`: Character encoding conversion error. `STRINGPREP_NFKC_FAILED`: The Unicode NFKC operation failed. This usually indicate an internal error in the library. `STRINGPREP_MALLOC_ERROR`: The malloc() was out of memory. This is usually a fatal error.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 78 of file strerror-stringprep.c.

5.23.4.10 `stringprep_ucs4_nfkc_normalize()`

```
IDNAPI uint32_t* stringprep_ucs4_nfkc_normalize (
    const uint32_t * str,
    ssize_t len )
```

`stringprep_ucs4_nfkc_normalize`:

Parameters

<code>str</code>	a Unicode string.
<code>len</code>	length of @str array, or -1 if @str is nul-terminated.

Converts a UCS4 string into canonical form, see [stringprep_utf8_nfkc_normalize\(\)](#) for more information.

Return value: a newly allocated Unicode string, that is the NFKC normalized form of @str.

Definition at line 1096 of file nfkc.c.

5.23.4.11 `stringprep_ucs4_to_utf8()`

```
IDNAPI char* stringprep_ucs4_to_utf8 (
    const uint32_t * str,
```

```
    ssize_t len,
    size_t * items_read,
    size_t * items_written )
```

stringprep_ucs4_to_utf8:

Parameters

<i>str</i>	a UCS-4 encoded string
<i>len</i>	the maximum length of @str to use. If @len < 0, then the string is terminated with a 0 character.
<i>items_read</i>	location to store number of characters read or NULL.
<i>items_written</i>	location to store number of bytes written or NULL. The value here stored does not include the trailing 0 byte.

Convert a string from a 32-bit fixed width representation as UCS-4. to UTF-8. The result will be terminated with a 0 byte.

Return value: a pointer to a newly allocated UTF-8 string. This value must be deallocated by the caller. If an error occurs, NULL will be returned.

Definition at line 1039 of file nfkc.c.

5.23.4.12 stringprep_unichar_to_utf8()

```
IDNAPI int stringprep_unichar_to_utf8 (
    uint32_t c,
    char * outbuf )
```

stringprep_unichar_to_utf8:

Parameters

<i>c</i>	a ISO10646 character code
<i>outbuf</i>	output buffer, must have at least 6 bytes of space. If NULL, the length will be computed and returned and nothing will be written to @outbuf.

Converts a single character to UTF-8.

Return value: number of bytes written.

Definition at line 982 of file nfkc.c.

5.23.4.13 stringprep_utf8_nfkc_normalize()

```
IDNAPI char* stringprep_utf8_nfkc_normalize (
    const char * str,
    ssize_t len )
```

stringprep_utf8_nfkc_normalize:

Parameters

<i>str</i>	a UTF-8 encoded string.
<i>len</i>	length of @str, in bytes, or -1 if @str is nul-terminated.

Converts a string into canonical form, standardizing such issues as whether a character with an accent is represented as a base character and combining accent or as a single precomposed character.

The normalization mode is NFKC (ALL COMPOSE). It standardizes differences that do not affect the text content, such as the above-mentioned accent representation. It standardizes the "compatibility" characters in Unicode, such as SUPERSCRIPT THREE to the standard forms (in this case DIGIT THREE). Formatting information may be lost but for most text operations such characters should be considered the same. It returns a result with composed forms rather than a maximally decomposed form.

Return value: a newly allocated string, that is the NFKC normalized form of @str.

Definition at line 1068 of file nfkc.c.

5.23.4.14 stringprep_utf8_to_locale()

```
IDNAPI char* stringprep_utf8_to_locale (
    const char * str )
```

stringprep_utf8_to_locale:

Parameters

<i>str</i>	input zero terminated string.
------------	-------------------------------

Convert string encoded in UTF-8 into the locale's character set by using [stringprep_convert\(\)](#).

Return value: Returns newly allocated zero-terminated string which is @str transcoded into the locale's character set.

Definition at line 161 of file toutf8.c.

5.23.4.15 stringprep_utf8_to_ucs4()

```
IDNAPI uint32_t* stringprep_utf8_to_ucs4 (
    const char * str,
    ssize_t len,
    size_t * items_written )
```

stringprep_utf8_to_ucs4:

Parameters

<i>str</i>	a UTF-8 encoded string
<i>len</i>	the maximum length of @str to use. If @len < 0, then the string is nul-terminated.
<i>items_written</i>	location to store the number of characters in the result, or NULL.

Convert a string from UTF-8 to a 32-bit fixed width representation as UCS-4. The function now performs error checking to verify that the input is valid UTF-8 (before it was documented to not do error checking).

Return value: a pointer to a newly allocated UCS-4 string. This value must be deallocated by the caller.

Definition at line 1006 of file nfkc.c.

5.23.4.16 stringprep_utf8_to_unichar()

```
IDNAPI uint32_t stringprep_utf8_to_unichar (
    const char * p )
```

stringprep_utf8_to_unichar:

Parameters

<i>p</i>	a pointer to Unicode character encoded as UTF-8
----------	---

Converts a sequence of bytes encoded as UTF-8 to a Unicode character. If does not point to a valid UTF-8 encoded character, results are undefined.

Return value: the resulting character.

Definition at line 965 of file nfkc.c.

5.24.2 Function Documentation

5.24.2.1 [tld_check_4\(\)](#)

```
int tld_check_4 (
    const uint32_t * in,
    size_t inlen,
    size_t * errpos,
    const Tld\_table ** overrides )
```

[tld_check_4](#):

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the code points in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 359 of file tld.c.

5.24.2.2 tld_check_4t()

```
int tld_check_4t (
    const uint32_t * in,
    size_t inlen,
    size_t * errpos,
    const Tld_table * tld )
```

tld_check_4t:

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>errpos</i>	Position of offending character is returned here.
<i>tld</i>	A Tld_table data structure representing the restrictions for which the input should be tested.

Test each of the code points in @in for whether or not they are allowed by the data structure in @tld, return the position of the first character for which this is not the case in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 280 of file tld.c.

5.24.2.3 tld_check_4tz()

```
int tld_check_4tz (
    const uint32_t * in,
    size_t * errpos,
    const Tld_table * tld )
```

tld_check_4tz:

Parameters

<i>in</i>	Zero terminated array of unicode code points to process.
<i>errpos</i>	Position of offending character is returned here.
<i>tld</i>	A Tld_table data structure representing the restrictions for which the input should be tested.

Test each of the code points in @in for whether or not they are allowed by the data structure in @tld, return the position of the first character for which this is not the case in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 322 of file tld.c.

5.24.2.4 tld_check_4z()

```
int tld_check_4z (
    const uint32_t * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_4z:

Parameters

<i>in</i>	Zero-terminated array of unicode code points to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the code points in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 409 of file tld.c.

5.24.2.5 tld_check_8z()

```
int tld_check_8z (
    const char * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_8z:

Parameters

<i>in</i>	Zero-terminated UTF8 string to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the characters in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the

information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos. Note that the error position refers to the decoded character offset rather than the byte position in the string.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all characters are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 446 of file tld.c.

5.24.2.6 tld_check_lz()

```
int tld_check_lz (
    const char * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_lz:

Parameters

<i>in</i>	Zero-terminated string in the current locales encoding to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the characters in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos. Note that the error position refers to the decoded character offset rather than the byte position in the string.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all characters are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 491 of file tld.c.

5.24.2.7 tld_default_table()

```
const Tld_table* tld_default_table (
    const char * tld,
    const Tld_table ** overrides )
```

tld_default_table:

Parameters

<i>tld</i>	TLD name (e.g. "com") as zero terminated ASCII byte string.
<i>overrides</i>	Additional zero terminated array of Tld_table info-structures for TLDs, or NULL to only use library default tables.

Get the TLD table for a named TLD, using the internal defaults, possibly overridden by the (optional) supplied tables.

Return value: Return structure corresponding to TLD @tld_str, first looking through @overrides then thru built-in list, or NULL if no such structure found.

Definition at line 89 of file tld.c.

5.24.2.8 tld_get_4()

```
int tld_get_4 (
    const uint32_t * in,
    size_t inlen,
    char ** out )
```

tld_get_4:

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out.

Return value: Return TLD_SUCCESS on success, or the corresponding [TId_rc](#) error code otherwise.

Definition at line 122 of file tld.c.

5.24.2.9 tld_get_4z()

```
int tld_get_4z (
    const uint32_t * in,
    char ** out )
```

tld_get_4z:

Parameters

<i>in</i>	Zero terminated array of unicode code points to process.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out.

Return value: Return TLD_SUCCESS on success, or the corresponding [TId_rc](#) error code otherwise.

Definition at line 171 of file tld.c.

5.24.2.10 tld_get_table()

```
const Tld_table* tld_get_table (
    const char * tld,
    const Tld_table ** tables )
```

tld_get_table:

Parameters

<i>tld</i>	TLD name (e.g. "com") as zero terminated ASCII byte string.
<i>tables</i>	Zero terminated array of Tld_table info-structures for TLDs.

Get the TLD table for a named TLD by searching through the given TLD table array.

Return value: Return structure corresponding to TLD @tld by going thru @tables, or return NULL if no such structure is found.

Definition at line 60 of file tld.c.

5.24.2.11 tld_get_z()

```
int tld_get_z (
    const char * in,
    char ** out )
```

tld_get_z:

Parameters

<i>in</i>	Zero terminated character array to process.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out. The input string @in may be UTF-8, ISO-8859-1 or any ASCII compatible character encoding.

Return value: Return TLD_SUCCESS on success, or the corresponding [Tld_rc](#) error code otherwise.

Definition at line 197 of file tld.c.

5.25.4 Function Documentation

5.25.4.1 tld_check_4()

```
IDNAPI int tld_check_4 (
    const uint32_t * in,
    size_t inlen,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_4:

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the code points in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 359 of file tld.c.

5.25.4.2 tld_check_4t()

```
IDNAPI int tld_check_4t (
    const uint32_t * in,
    size_t inlen,
    size_t * errpos,
    const Tld_table * tld )
```

tld_check_4t:

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>errpos</i>	Position of offending character is returned here.
<i>tld</i>	A Tld_table data structure representing the restrictions for which the input should be tested.

Test each of the code points in @in for whether or not they are allowed by the data structure in @tld, return the position of the first character for which this is not the case in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_←INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 280 of file tld.c.

5.25.4.3 tld_check_4tz()

```
IDNAPI int tld_check_4tz (
    const uint32_t * in,
    size_t * errpos,
    const Tld_table * tld )
```

tld_check_4tz:

Parameters

<i>in</i>	Zero terminated array of unicode code points to process.
<i>errpos</i>	Position of offending character is returned here.
<i>tld</i>	A Tld_table data structure representing the restrictions for which the input should be tested.

Test each of the code points in @in for whether or not they are allowed by the data structure in @tld, return the position of the first character for which this is not the case in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_←INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 322 of file tld.c.

5.25.4.4 tld_check_4z()

```
IDNAPI int tld_check_4z (
    const uint32_t * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_4z:

Parameters

<i>in</i>	Zero-terminated array of unicode code points to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the code points in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all code points are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 409 of file tld.c.

5.25.4.5 tld_check_8z()

```
IDNAPI int tld_check_8z (
    const char * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_8z:

Parameters

<i>in</i>	Zero-terminated UTF8 string to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the characters in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos. Note that the error position refers to the decoded character offset rather than the byte position in the string.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all characters are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 446 of file tld.c.

5.25.4.6 tld_check_lz()

```
IDNAPI int tld_check_lz (
    const char * in,
    size_t * errpos,
    const Tld_table ** overrides )
```

tld_check_lz:

Parameters

<i>in</i>	Zero-terminated string in the current locales encoding to process.
<i>errpos</i>	Position of offending character is returned here.
<i>overrides</i>	A Tld_table array of additional domain restriction structures that complement and supersede the built-in information.

Test each of the characters in @in for whether or not they are allowed by the information in @overrides or by the built-in TLD restriction data. When data for the same TLD is available both internally and in @overrides, the information in @overrides takes precedence. If several entries for a specific TLD are found, the first one is used. If @overrides is NULL, only the built-in information is used. The position of the first offending character is returned in @errpos. Note that the error position refers to the decoded character offset rather than the byte position in the string.

Return value: Returns the [Tld_rc](#) value TLD_SUCCESS if all characters are valid or when @tld is null, TLD_INVALID if a character is not allowed, or additional error codes on general failure conditions.

Definition at line 491 of file tld.c.

5.25.4.7 tld_default_table()

```
IDNAPI const Tld_table* tld_default_table (
    const char * tld,
    const Tld_table ** overrides )
```

tld_default_table:

Parameters

<i>tld</i>	TLD name (e.g. "com") as zero terminated ASCII byte string.
<i>overrides</i>	Additional zero terminated array of Tld_table info-structures for TLDs, or NULL to only use library default tables.

Get the TLD table for a named TLD, using the internal defaults, possibly overridden by the (optional) supplied tables.

Return value: Return structure corresponding to TLD @tld_str, first looking through @overrides then thru built-in list, or NULL if no such structure found.

Definition at line 89 of file tld.c.

5.25.4.8 tld_get_4()

```
IDNAPI int tld_get_4 (
    const uint32_t * in,
    size_t inlen,
    char ** out )
```

tld_get_4:

Parameters

<i>in</i>	Array of unicode code points to process. Does not need to be zero terminated.
<i>inlen</i>	Number of unicode code points.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out.

Return value: Return TLD_SUCCESS on success, or the corresponding [Tld_rc](#) error code otherwise.

Definition at line 122 of file tld.c.

5.25.4.9 tld_get_4z()

```
IDNAPI int tld_get_4z (
    const uint32_t * in,
    char ** out )
```

tld_get_4z:

Parameters

<i>in</i>	Zero terminated array of unicode code points to process.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out.

Return value: Return TLD_SUCCESS on success, or the corresponding [Tld_rc](#) error code otherwise.

Definition at line 171 of file tld.c.

5.25.4.10 tld_get_table()

```
IDNAPI const Tld_table* tld_get_table (
    const char * tld,
    const Tld_table ** tables )
```

tld_get_table:

Parameters

<i>tld</i>	TLD name (e.g. "com") as zero terminated ASCII byte string.
<i>tables</i>	Zero terminated array of Tld_table info-structures for TLDs.

Get the TLD table for a named TLD by searching through the given TLD table array.

Return value: Return structure corresponding to TLD @tld by going thru @tables, or return NULL if no such structure is found.

Definition at line 60 of file tld.c.

5.25.4.11 tld_get_z()

```
IDNAPI int tld_get_z (
    const char * in,
    char ** out )
```

tld_get_z:

Parameters

<i>in</i>	Zero terminated character array to process.
<i>out</i>	Zero terminated ascii result string pointer.

Isolate the top-level domain of @in and return it as an ASCII string in @out. The input string @in may be UTF-8, ISO-8859-1 or any ASCII compatible character encoding.

Return value: Return TLD_SUCCESS on success, or the corresponding [Tld_rc](#) error code otherwise.

Definition at line 197 of file tld.c.

5.25.4.12 tld_strerror()

```
IDNAPI const char* tld_strerror (
    Tld_rc rc )
```

tld_strerror:

Parameters

<i>rc</i>	tld return code
-----------	-----------------

Convert a return code integer to a text string. This string can be used to output a diagnostic message to the user.

TLD_SUCCESS: Successful operation. This value is guaranteed to always be zero, the remaining ones are only guaranteed to hold non-zero values, for logical comparison purposes. TLD_INVALID: Invalid character found. TLD_NODATA: No input data was provided. TLD_MALLOC_ERROR: Error during memory allocation. TLD_ICONV_ERROR: Character encoding conversion error. TLD_NO_TLD: No top-level domain found in domain string.

Return value: Returns a pointer to a statically allocated string containing a description of the error with the return code @rc.

Definition at line 59 of file strerror-tld.c.

{
    &_tld_fr,
    &_tld_no,
    NULL
}
```

Definition at line 60 of file tlids.c.

5.27 toutf8.c File Reference

```
#include "stringprep.h"
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "striconv.h"
#include <locale.h>
```

Functions

- const char * `stringprep_locale_charset` (void)
- char * `stringprep_convert` (const char *`str`, const char *`to_codeset`, const char *`from_codeset`)
- char * `stringprep_locale_to_utf8` (const char *`str`)
- char * `stringprep_utf8_to_locale` (const char *`str`)

5.27.1 Function Documentation

5.27.1.1 `stringprep_convert()`

```
char* stringprep_convert (
    const char * str,
    const char * to_codeset,
    const char * from_codeset )
```

`stringprep_convert`:

Parameters

<i>str</i>	input zero-terminated string.
<i>to_codeset</i>	name of destination character set.
<i>from_codeset</i>	name of origin character set, as used by @str.

Convert the string from one character set to another using the system's iconv() function.

Return value: Returns newly allocated zero-terminated string which is @str transcoded into to_codeset.

Definition at line 116 of file toutf8.c.

5.27.1.2 stringprep_locale_charset()

```
const char* stringprep_locale_charset (
    void )
```

stringprep_locale_charset:

Find out current locale charset. The function respect the CHARSET environment variable, but typically uses nl_langinfo(CODESET) when it is supported. It fall back on "ASCII" if CHARSET isn't set and nl_langinfo isn't supported or return anything.

Note that this function return the application's locale's preferred charset (or thread's locale's preferred charset, if your system support thread-specific locales). It does not return what the system may be using. Thus, if you receive data from external sources you cannot in general use this function to guess what charset it is encoded in. Use stringprep_convert from the external representation into the charset returned by this function, to have data in the locale encoding.

Return value: Return the character set used by the current locale. It will never return NULL, but use "ASCII" as a fallback.

Definition at line 85 of file toutf8.c.

5.27.1.3 stringprep_locale_to_utf8()

```
char* stringprep_locale_to_utf8 (
    const char * str )
```

stringprep_locale_to_utf8:

Parameters

<i>str</i>	input zero terminated string.
------------	-------------------------------

Convert string encoded in the locale's character set into UTF-8 by using [stringprep_convert\(\)](#).

Return value: Returns newly allocated zero-terminated string which is @str transcoded into UTF-8.

Definition at line 145 of file toutf8.c.

5.27.1.4 stringprep_utf8_to_locale()

```
char* stringprep_utf8_to_locale (
    const char * str )
```

stringprep_utf8_to_locale:

Parameters

<code>str</code>	input zero terminated string.
------------------	-------------------------------

Convert string encoded in UTF-8 into the locale's character set by using [stringprep_convert\(\)](#).

Return value: Returns newly allocated zero-terminated string which is @str transcoded into the locale's character set.

Definition at line 161 of file toutf8.c.

5.28 version.c File Reference

#include "stringprep.h"
#include <string.h>
```

Functions

- `const char * stringprep_check_version (const char *req_version)`

5.28.1 Function Documentation

5.28.1.1 stringprep_check_version()

```
const char* stringprep_check_version (
    const char * req_version )
```

stringprep_check_version:

Parameters

<i>req_version</i>	Required version number, or NULL.
--------------------	-----------------------------------

Check that the version of the library is at minimum the requested one and return the version string; return NULL if the condition is not satisfied. If a NULL is passed to this function, no check is done, but the version string is simply returned.

See STRINGPREP_VERSION for a suitable @req_version string.

Return value: Version string of run-time library, or NULL if the run-time library does not meet the required version number.

Definition at line 53 of file version.c.
